The field data and laboratory tests described above suggest that with restricted access to salt the growth of vole populations may be checked at relatively low levels by physiological responses associated with crowding, and that with unrestricted access to salt the suppressive effects of crowding are alleviated, allowing populations to increase.

higher levels. Implied in these deductions is the principle that sodium is the critical factor limiting vole populations in many areas. In regions with high sodium, enough salt may be ingested with the vegetation to satisfy the increased requirements of crowded animals, thereby permitting unrestricted reproduction and population growth to the point where food or some other factor becomes critical.

Simple Technique for embedding and supporting Delicate Biological Specimens

MANY biological specimens are too large for treatment by normal microscopical techniques and, at the same time, too small and delicate to withstand very much manipulation. Many embedding media have been tried in the past few years, and one of the most efficient and effective is agar.

A 4 per cent aqueous (distilled water) solution of agar (Difco Laboratories) is prepared, either by free boiling in an autoclave or steamer, or by using a beaker suspended in a boiling water bath. The molten agar is cooled to about 40° C and a thin layer poured onto a solid watch-glass and allowed to set. The specimen is arranged on the surface of the agar and is then covered by a further layer of molten agar. It is important to ensure that no moisture is left on the first layer. Moisture bubbles will spread between the two layers and can cause separation after setting. This trouble is obviated by wiping the specimen and the surface of the agar with a small piece of filter paper after the specimen has been tented. When the agar has set, the lens-shaped block is eased out of the watch-glass and the part containing the specimen trimmed into a cubical block, using a sharp scalpel or razor blade. The cube (which is opaque when set) is then transferred to 70 per cent alcohol, in which it may be stored until required for clearing. For clearing, the block is gradually dehydrated by being taken through 70 per cent, 90 per cent and absolute alcohol, one day in each, and then transferred to a mixture of equal parts of absolute alcohol and benzyl alcohol for a few hours. It is then removed to pure benzyl alcohol for complete clearing. Both block and specimen will become transparent quite quickly but specimens containing a great deal of yolk may require a longer time to achieve complete transparency. In the case of amphibian eggs this is an advantage because the slight opacity gives a clearer picture of the segmentation stages.

The technique is particularly useful for eggs of cyclopoidea, teleost fishes and amphibia, coelenterate medusae, cross-sections of small molluscs and molluscan radulae too large for ordinary microscope mounts. Specimens may be stained before embedding, but they must be returned to water before processing. Blocks may be removed from the benzyl alcohol for examination under a dissecting microscope, but should not be kept in the air for a period of more than 3 h, otherwise splitting and drying of the block may occur. All material for treatment under these conditions must first be fixed and preserved as for normal storage. The blocks are tough and resistant to wear, but should it be necessary to remove a specimen from a block a careful cut across a block in one plane will enable the specimen to be removed without damage. All parings from the first trimming may be remelted and

used for more blocks. Agar cannot be recovered after treatment with alcohol.

Selective Effect of Particulate Insecticides on *Simulium* among Stream Fauna

Simulium, the vector of onchocerciasis and the cause of considerable nuisance in northern latitudes, is usually controlled by killing its aquatic stages by putting insecticides in a soluble form into the streams where they occur. This kills most of the other insects; the natural predatory suppressors of the *Simulium* larvae—the larvae of some of the stone flies and caddis flies—are removed, and unrestrained recolonization by *Simulium* may occur.

The community of creatures living in fresh-water streams is highly organized and stable and constitutes many food chains, one ending in fish. The use of soluble DDT necessitates repetition and produces an entirely different organization, the maintenance of which is dependent on the maintenance of the interference. This changed environment can be regarded in many respects as biologically sterile.

Simulium larvae are particle feeders. They live only in the fast-flowing parts of the stream, and their method of feeding is different from that of the other detritus feeders such as the chironomids, which live in the slow-running and silted part of the stream. The size of particles ingested by British species of *Simulium* is about 10–12 μ (ref. 1). Since 1962, we have used DDT in the form of particles of different size in streams in North Wales. In one such experiment, 1×10^{12} particles of 4–15 μ were put into a stream in half an hour, when the stream was flowing at a rate of 0.15 cu. ft./sec. This corresponded to a dosage of 0.5 p.p.m. The next day, all *Simulium* larvae had disappeared from polythene tapes placed 150 yards below the point of dosage, and the tapes remained free of *Simulium* until a month after the dosing. During this time no other creatures in either the water or the stream bed showed any population variation other than the minor fluctuations expected from the changing seasons and rainfall. Not even net-spinning caddis fly larvae were affected by the small particles of DDT.

It is possible that a method of control developed on this principle will not disturb the predator insects which regulate the numbers of *Simulium* larvae, and it should not interfere with the tightly knit community of creatures which includes the food chain leading to fish. But we do not know whether the particulate insecticide accumulates in the sediment of the river bed, nor do we know anything of the potential effects of such accumulation, and we know nothing of the fate of that fraction which is taken up by *Simulium* larvae. These and other factors must be investigated.

We wish to thank "Shell" Research, Ltd., Woodstock Agricultural Research Centre, for providing water dispersible powders of the required particle size.

MICROBIOLOGY

Bacterial Count and Cell Differentiation in Milk

A METHOD has been developed in this laboratory which has been found to be superior to the Breed-type smears such as are routinely used for assessing the bacteriological quality of cow's milk. The technique not only stains the bacteria, but also the somatic cells in such a way that the various cell-types may be satisfactorily differentiated and classified. Granular cytoplasmic inclusions which might be released on cell-degeneration are easily distinguished and not mistaken for the coccoid form of micro-organisms.

The use of 0.2 ml. of sample instead of 0.01 ml. (as in the Breed-method and its modifications), even distribution and low microscopic factor improves the precision of the count.

The fact that the cells are differentiated will help the investigator who is not only concerned with a total count to distinguish between pathological and normal conditions of the udder. The micro-organisms and the cells present in the milk sample are stained in a siliconed serological tube. This stained preparation is filtered, by vacuum filtration, through a membrane filter (M.F. Corp. plain white D.A.; diam., 25 mm; pore size, 0.65 μ). This filter, after being dried, is made transparent with immersion oil and the bacteria and cells can then be counted and studied with a light microscope.

The procedure is as follows: 2 ml. 'Triton X-100', 0.1 per cent solution, pH 7.0 (prepared with double distilled water and filtered through a membrane filter), is placed in a serological tube. 2-3 drops 0.5 per cent solution $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ is added. Three drops benzidine-peroxide solution is added (benzidine 0.2 g/200 ml. distilled water; to which is added 4 drops of H_2O_2 , 3 per cent). The milk sample (0.2 ml.) is added, and the mixture allowed to stand for 3 min. One drop of May-Grünwald stain (BDH standard stain in solution) is added, with 2 drops of Giemsa stain (improved Giemsa stain, Gurr R66 in solution). The tube is stood for 20 min in a water bath at 48° C, then poured into a filter funnel; two rinsings of the serological tube with 'Triton' solution at 48° C are also poured into the funnel. Vacuum is applied to pull the emulsion through the membrane filter. Rinsing is accomplished by flushing about 7 ml. 'Triton' solution (at 48° C) through the filter. The membrane filter is removed and dried on a glass slide at 35° C for about 10 min; immersion oil is added until the membrane filter becomes transparent. It is then covered with a cover slip. Another drop of immersion oil is placed on the cover slip, and the preparation is examined under the microscope.

I thank Prof. A. G. Leggatt for his advice.

Formation of Protocatechuic from Quinic Acid by Fluorescent Pseudomonads

ROGOFF¹ described two fluorescent pseudomonads he electively isolated from soil which could oxidize quinic acid with the formation of protocatechuic acid as an intermediate.

Fifty-two isolates, assignable to the genus *Pseudomonas* and producing pyoverdine in the medium of King, Ward and Raney², have been examined for their ability to aromatize quinic acid by this pathway. The strains were isolated from infected hen-eggs, surface waters, chicken carcasses, chicken droppings, beef and milk, using ordinary peptone media containing no quinate.

Protocatechuic formation by the isolates was investigated in the following medium, adapted from that of

Rogoff¹: Solution A. NH_4Cl , 0.4 g; $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, 0.05 g; $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$, 0.01 g; $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$, 0.001 g; CaCO_3 , 0.2 g; yeast extract (Difco), 0.05 g; agar N (Oxoid), 0.05 g; distilled water, 50 ml., pH 7.4. Solution B. K_2HPO_4 , 0.1 g; quinic acid, 1.0 g; distilled water, 50 ml., pH 7.4 (adjusted with 10 per cent (w/v) NaOH). The two solutions were mixed, dispensed in 2-ml. amounts into test-tubes (100 mm \times 10 mm) and autoclaved 15 min at 15 lb. pressure. One drop from broth culture of the 52 strains was used to inoculate the quinate medium. On incubation at 25°, protocatechuic acid was readily detected by the formation of a purple colour below bacterial surface growth due to the action of ferrous ions on this compound. In most such cases, a green colour also appeared at the medium surface: this may have been due to the reaction of protocatechuic acid with ferrous ions, formed at the medium surface by oxidation of ferrous ions (Soloway and Rosen³), but since this zone fluoresces strongly it may simply have been pyoverdine produced on the surface of the medium. A drop of medium removed from the purple portion of each culture did, however, form a deep green colour on the addition of a drop of aqueous 0.5 per cent (w/v) $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$. By these tests, protocatechuic acid was discernible in the culture within 2-3 days; after a week or so, the purple colour slowly disappeared and no ferric chloride reaction could be demonstrated.

Of the 52 fluorescent pseudomonads, 49 produced protocatechuic acid. The three negative strains (from river water, chicken droppings and spoiling beef respectively) grew more sparsely on the medium, utilizing the yeast extract as a carbon source, presumably. An interesting biochemical characteristic these three strains shared was the ability to decarboxylate L-glutamic acid to γ -aminobutyric acid; one of the other strains was also able to carry out this reaction but it possessed in addition L-aspartic acid decarboxylase.

Manometric experiments with washed cell suspensions gathered after 60 h growth on the quinate medium (solidified with 1.5 per cent w/v agar) demonstrated oxygen uptake by the three strains in the presence of sodium quinate (pH 7.4, 30°), whereas representatives of the other 49 strains rapidly oxidized this substrate.

It would seem that fluorescent pseudomonads commonly possess the ability to oxidize quinic acid via protocatechuic acid but that some strains are unable to attack it by this or any other pathway. Since the formation of protocatechuic acid can be easily demonstrated in growing cultures by its reactions with ferrous and ferric ions, and since a significant number of strains do not effect production, the test should prove a useful one for inclusion in taxometric methods for the sub-grouping of *Pseudomonas*. It has been found that the use of a solid medium favours the accumulation of the protocatechuic acid formed in the region below the surface growth and prevents its too rapid oxidation.

VIROLOGY

Rubella Virus Complement-fixation Test

METHODS in present use for the serological diagnosis of rubella consist of the neutralization^{1,2} and the indirect fluorescent-antibody³ techniques. The former is expensive and laborious and requires usually 7-10 days to carry out, while the latter, although it can give an answer within a matter of hours, is a difficult technique for routine

agnosis. The preparation of a complement-fixing antigen recently been described⁴, providing for a rapid and simple test of infection. The antigen, which is cell-associated, was made in the RK₁₃ line of rabbit kidney cells or in primary cultures of kidney from the African green monkey. The infected cells were processed 2 days and 7–10 days respectively after inoculation of virus. Successful antigen preparation, however, is in both cases dependent on a critically large virus inoculum; otherwise results are erratic. The present report describes a simpler and more reliable method of complement-fixing antigen preparation, involving the use of aged cultures of a chronically infected line of LLO-MK₂ cells⁵.

The chronically infected cells were grown in Roux bottles in Medium 199 containing 1 per cent inactivated horse serum and antibiotics and adjusted to pH 7.4 with sodium bicarbonate. The cultures were maintained by replacing half the medium every 3–4 days. Antigen was prepared at intervals by discarding the medium and scraping the cells from the glass into a small volume of Rönal-buffered saline. The cells were sedimented by centrifuging at 1,000 r.p.m. for 10 min, and resuspended in buffer to a final volume equivalent to 1 ml. per Roux bottle. This cell suspension was then frozen and thawed three times, or subjected to ultrasonic vibrations for 15 sec. The final product constitutes the antigen. The technique is similar to that used in preparing cytomegalovirus complement-fixing antigen⁶. The antigen can be stored at -70° C for at least 1 month without loss of potency. Activity is lost at 56° C within 0.5 h. Because of the relatively small amounts of antigen available, complement-fixation tests were carried out by the micro-technique, using 0.025-ml. Takatsy loops, micropipettes and 'Perspex' plates⁷. Each batch of antigen was examined in a chess-board titration against a positive control convalescent serum, using 2 units of complement and overnight fixation at 4° C.

Little or no antigenic activity was demonstrable in preparations from cell cultures less than 7 days old. Antigenicity first became detectable with 7–14-day-old cultures but the titres, measured as the reciprocal of the greatest dilution of antigen showing at least 3+ complement fixation with the positive serum, did not exceed 2. Maximum antigen titres of 8 were, however, reached after 4 days of incubation of the cell cultures. The material showed no or only minimal anticomplementary activity when used undiluted. While Sever *et al.*⁴ briefly mention in their paper the preparation of complement-fixing antigen from the chronically infected LLO-MK₂ cells, they apparently found no advantage with this technique and no details are given. The present findings indicate that with aged cells as described here the antigen potency is at least equivalent to that produced in RK₁₃ and primary African green monkey kidney cells. Although prolonged incubation of the chronically infected cells is required for antigen manufacture, the initial preparation of large inoculum doses of virus becomes unnecessary and, in our experience, potent antigens are obtained regularly.

Table 1 shows the results observed with a number of sera from children and adults. All sera for complement-fixation tests were inactivated by 56° C, and were titrated against 2 units of antigen. The tests were controlled with known positive and negative sera. Neutralizing antibody titres were measured in RK₁₃ cells. Serial dilutions of non-inactivated sera were mixed with equal volumes of a suspension of the Judith strain of rubella virus containing 100 TCID₅₀ per 0.1 ml., and the mixtures were incubated at 37° C for 1 h. Tissue culture tubes were then inoculated with 0.2 ml. amounts of the serum-virus mixtures, and incubated at 33° C in a roller drum. The tubes were examined for cytopathic effects over a period of 14 days. The neutralizing antibody titres were calculated as the reciprocal of the highest dilution of serum which completely suppressed the cytopathic effect of the virus.

Table 1. ANTIBODY RESPONSES IN PATIENTS WITH RUBELLA VIRUS INFECTION

* After onset of rash.

† Virus isolated from throat and faeces.

‡ Virus isolated from urine and throat.

§ Not excreting virus.

While only a few cases of clinical rubella have so far been investigated with the complement-fixation test, it is apparent that the complement-fixing antibody develops in parallel with the neutralizing antibody but is delayed by several days. The latter antibody is already detectable in most cases by the second day after the onset of the rash^{1,2}, whereas the complement-fixing antibody probably does not appear until about the fifth day. The presence of neutralizing antibody without complement-fixing antibody in adults who give no recent history of rubella suggests that the complement-fixing antibody is transient⁴. The neutralization test will therefore still be necessary for the detection of past infection and for epidemiological studies. The three cases of rubella syndrome illustrate three different and interesting antibody situations. The first case possesses only neutralizing antibody, despite active infection and virus excretion. However, inability to make complement-fixing antibody is not uncommon in small infants in many other virus infections. The 8-month-old case shows both types of antibody, perhaps because of greater maturity and continued infection. The 2.5-year-old case has ceased to excrete virus, and no longer possesses demonstrable complement-fixing antibody. This disease differs, therefore, from cytomegalovirus and herpes virus infections, and the findings in this child appear to suggest that there is no persistent latent infection with rubella virus in children with the rubella syndrome.

The complement-fixation test provides an easy and rapid method of serological investigation of recent rubella virus infection, and should contribute to a more complete understanding of the pathogenesis and epidemiology of this common and important disease.

GENETICS

Phenocopies of the *ma-l* and *ry* Mutants of *Drosophila melanogaster*: Inhibition *in vivo* of Xanthine Dehydrogenase by 4-Hydroxypyrazolo(3,4-d)pyrimidine

PHENOCOPIES are environmentally induced abnormalities which mimic the phenotype resulting from mutant genes. Pomaies *et al.*¹ have shown that 4-hydroxypyrazolo(3,4-d)pyrimidine (HPP) is an inhibitor *in vivo* of xanthine oxidase in mice, and we have attempted to produce phenocopies of the maroon-like (*ma-l*) and rosy (*ry*) eye colour mutants of *Drosophila melanogaster* with it. Xanthine dehydrogenase is undetectable in these mutants (see Glassman² for a discussion of these loci), and as a result, there is a partial loss of the red pteridines of the eye, the eyes being a dark red-brown rather than red. In addition, the products of this enzyme's activity, isoxanthopterin and uric acid, cannot be detected, and its substrates, 2-amino-4-hydroxypteridine and hypoxanthine, accumulate. In this communication we describe the production of phenocopies of *ma-l* and *ry* by HPP in various strains of *D. melanogaster*.

The medium on which the flies were raised was modified from one described by Dr. E. B. Lewis (personal communication). 100 ml. medium was prepared by adding 1.7 g brewer's yeast, 5.7 g dextrose, 1.4 g sucrose, 9.4 g fine-ground yellow corn meal, 0.6 g agar, and 1.0 ml. food colouring (for identification) to 94 ml. water at 85° C. The mixture was heated to 95° C until it started to thicken. When it had cooled to 70° C, 1.2 ml. of 3 per cent benzyl benzoate (Eastman) in 95 per cent ethanol (to control mites), 1.0 ml. of a mixture containing 41.8 ml. propionic acid, 4.15 ml. phosphoric acid (85 per cent), and water to 100 ml. (to control mould), and the desired amount of HPP were added. The medium was then mixed in a Waring blender and 10-ml. portions were dispensed into 25 × 95 mm vials. The next day, adult flies were placed in each vial and allowed to deposit eggs on the surface of the medium for 3 to 4 days. Flies were reared at 25° ± 1° C.

Eye colours were recorded daily when the adults emerged. In order to facilitate this a strain containing the scarlet eye colour gene (*st*) at locus 44 on the third chromosome was used. The *st* mutant lacks the brown eye pigment and the eye colour is usually bright red. The double mutant, *st ry* or *ma-l*; *st*, has a yellow-orange eye colour, and this is also the eye colour of the *st* flies which are phenocopies of *ma-l* and *ry*. For comparative purposes, the Pacific wild-type strain and the *ru lxd by* strain was also used (*ru* and *by* are the symbols for roughoid eye and blister wing, and are only incidental markers). The *ru lxd by* strain has relatively low xanthine dehydrogenase activity because of *lxd* (low xanthine dehydrogenase) at locus 33 ± on the third chromosome³. Only those flies that duplicate the *ma-l* or *ry* eye colour exactly (red-brown eye colour in the case of Pacific and *lxd*, and orange eye colour for *st*) were scored as phenocopies; those showing intermediate eye colours were scored as normal.

Fig. 1 shows the percentage of flies grown on different amounts of HPP that resembled the *ry* and *ma-l* mutants. In no instance did any of these phenocopy flies transmit their abnormal eye colour to their progeny grown on regular food. The concentration of HPP required to transform 50 per cent of the flies into phenocopies varied. For *ru lxd by* it was about 0.008 per cent, for *st* it was about 0.026 per cent, and for *PAC* it was about 0.095 per cent. This difference in response might be due to the average xanthine dehydrogenase activity found in these strains; for the *ru lxd by* it was 3.8, for *st* it was 10.0 and for *PAC* it was 22.4 enzyme units per fly as measured by the method of Glassman^{3,4}. However, additional work

Table 1. THE EFFECTS OF HPP ON THE *st* STRAIN OF *Drosophila melanogaster*

Conc. of HPP	% Flies with phenocopy eye colour	Relative survival	Relative amount of isoxanthopterin*	Xanthine dehydrogenase units per fly

0.10	—	0.02	0.5	—

* Data for *st*, *PAC*, and *ru lxd by* flies are combined for this column.

† The mean of 8 replicate assays of single flies

is required to substantiate this relationship. High doses of HPP have an appreciable detrimental effect on viability (Table 1).

To test whether the other pteridines (2-amino-4-hydroxypteridine and isoxanthopterin) related to xanthine dehydrogenase were also affected, flies were chromatographed by the following modification of the method of Hadorn and Mitchell⁵. A fly was placed in boiling water for 1 min and then squashed with a glass stirring rod on the origin of a 9 in. × 11 in. sheet of Whatman No. 3 *M* filter paper. The chromatograms were developed by ascending chromatography for about 4 h in propanol 1 per cent NH_4OH (2:1). When dry, the chromatograms were observed under an ultra-violet lamp emitting mair at 365 mμ. In order to quantitate these results, we applied an arbitrary visual grading system using '0' to represent the absence of isoxanthopterin and '4' to represent the highest amounts we observed. The grading was done on coded flies to eliminate bias. The data is presented in Table 1, where it can be seen that the amount of isoxanthopterin declined as the concentration of HPP increased. In contrast, 2-amino-4-hydroxypteridine was present in higher-than-usual amounts in the flies raised on the higher concentration of HPP. This indicates that the effect of HPP is on xanthine dehydrogenase and not directly on the eye colour or on pteridines.

Furthermore, HPP has no effect on the synthesis of this enzyme. Table 1 shows that the enzyme activity was not affected in *st* flies grown on HPP even though the flies grown on 0.030, 0.040 and 0.050 per cent HPP were phenocopies. It is concluded that the synthesis of xanthine dehydrogenase is not affected by HPP.

It is clear that HPP effectively inhibits xanthine dehydrogenase activity in *D. melanogaster*, *in vivo*. Furthermore, the effectiveness of HPP seems to be relatively inversely to the amount of enzyme activity present in each strain. This phenomenon will be useful in many ways (1) by suppressing the maternal effect of the *ma-*

Fig. 1. The effect of HPP on phenocopy production in the *lxd*, *st*, and *PAC* strains of *Drosophila melanogaster*

10⁶,⁷ with a low concentration of HPP in the food, we expedite the genetic analysis of the *ma-l* locus; (2) by using low concentrations of HPP in food and using the usual genetic selection techniques, it might be possible to select for new mutant alleles at the *lxd* locus, or for leaky mutants at the *ma-l* and *ry* loci; (3) the use of high levels of HPP in the food may facilitate the selection of strains of flies that have very high xanthine dehydrogenase activity. These applications are now being explored.

We thank Dr. George H. Hitchings of Burroughs Wellcome and Co. for his generous gift of HPP. This work was supported by a grant (GM-08202) from the National Institutes of Health, and by a U.S. Public Health Service research career development award M-K3-14, 911-C1).

Induction of Crossing-over in *Drosophila* Males by Means of Ovarian Extract

THE frequency of gene recombination is known to be affected by extrinsic factors or intrinsic ones such as sex. Crossing-over is completely blocked in dipteran males, including those of *Drosophila melanogaster*, and in silkworm males. It is a puzzling problem why sex should have such an influence on crossing-over. Lack of homology between regions of the X and Y may explain the absence of crossing-over between the sex-chromosomes of the heterogametic sex, but the absence of crossing-over in the autosomes must have a different cause.

All agents that so far have been found to produce crossing-over in *Drosophila* males—irradiation and certain chemicals—cause mutations and chromosomal aberrations as well. In the work recorded here, an attempt has been made to induce crossing-over in males by means of fresh ovarian extracts. Males and females utilized in this work were heterozygous for the second-chromosome markers dumpy (*dp*), black (*b*), cinnabar (*cn*), and brown (*bw*). About 300 ovaries of fertilized females were dissected into 0.3 c.c. of 0.4 per cent saline. The ovaries were then homogenized and centrifuged twice at 3,000 r.p.m. for 15–20 min. The supernatant was filtered and/or directly taken into a microsyringe, and 0.2 μ l. was injected into the testis region of males. A portion of the same or a similarly obtained supernatant was boiled before injection. Males injected with 0.4 per cent saline and untreated males served as additional controls. 24 h after injection, each male was individually mated with three virgin females homozygous for *dp b cn bw*, and six broods of three days each were analysed for induced cross-overs in *F*₁. Presumptive cross-overs were verified by back-crosses to the multiple recessive strain.

Table 1 presents a summary of the results. It will be seen that cross-overs occurred exclusively among the progeny of a proportion of those males that had been injected with fresh ovarian extract.

Table 2 presents an analysis of the progeny from the 25 males that had yielded cross-overs. The overall fre-

Total cross-overs					5	5	4	11	5

quency of crossing-over was 5 per cent. The distribution over the 3 chromosomal regions used did not correspond to the lengths of these regions, and there were great disparities between complementary classes; these unexpected features may, however, be due to the fact that sampling errors were greatly exaggerated by the occurrence of clusters. The brood pattern shows that, as in the experiments by Reddi and Auerbach¹, some of the spermatozoa utilized in brood B must have been pre-meiotic or in early meiosis at the time of treatment. The occurrence of some clusters in this brood would suggest the former possibility but, with the few markers used, apparent clusters may equally well have been due to independent cross-overs in several spermatocytes of the same male.

While the details of the observed effect require a more elaborate analysis, the results clearly indicate that fresh ovarian extract contains a factor that induces crossing-over in male germ cells. The ineffectiveness of boiled ovarian extract suggests that this factor is a heat-labile substance.

Regression of a Phenotypic Value on the Values for the Parents and Grandparents

THE problem discussed in this communication was suggested by Dr. Donald Michie in connexion with an investigation, by himself and Mrs. Jean Hayes, of pedigree records in British Bloodstock.

Let x be some phenotypic value for some animal, and let x^P be the average of the value for its two parents, and x^G that of its four grandparents. The problem is to find the regression of x on x^P and x^G , that is to find the partial regression coefficients $b_{HP.P}$ and $b_{HG.P}$ such that:

$$E(x|x^P, x^G) = b_{HP.P}x^P + b_{HG.P}x^G.$$

Write :

$$x = w + z, x^P = w^P + z^P, x^G = w^G + z^G,$$

where the w 's are 'environmental values' and the z 's are 'genotypic values'. We make the following assumptions, the first of which implies no real loss of generality, and the remainder are natural.

$$E(w) = 0, E(w) = E(z) = 0, \text{cov}(w, w^P) = \text{cov}(w, w^G) = \text{cov}(w, z) = \text{cov}(w, z^P) = \text{cov}(w, z^G) = 0.$$

We also assume that the conditions are stationary from generation to generation, and that:

$$E(z|z^P) = E(z|z^P, z^G) = z^P.$$

This last assumption means that the breeding (genotypic) properties of the parents supersede those of the grandparents, at any rate in regard to expectations.

Let h be the correlation coefficient between x and z . It is customary to call h^2 the 'heritability' of the relevant trait. It can then be proved, by making use of standard regression theory, that:

$$b_{HP.G} = h^2(1 - \frac{1}{2}h^2)/(1 - \frac{1}{2}h^4)$$

$$b_{HG.P} = h^2(1 - h^2)/(1 - \frac{1}{2}h^4)$$

AGRICULTURE

Objective Evaluation of Quality in Poultry Meat

RECENT work in this laboratory¹⁻⁵ has indicated a relation between biochemical and quality changes occurring in chicken muscle during storage. During frozen storage the buffer-extractable nitrogen of chicken muscle decreased and the products of protein breakdown increased¹. The decrease in buffer-extractable nitrogen occurred as a result of loss of solubility of the actomyosin fraction and was accompanied by a loss of sulphydryl groups (-SH) of muscle tissue. During storage at above-freezing temperatures, extensive proteolysis occurred, but the changes in the protein extractability and -SH group content of muscle tissue were small². In meat in which the proteolytic activity had been destroyed by cooking, the -SH groups of muscle tissue decreased progressively during frozen storage without any increase in the protein-breakdown products³. The loss of -SH groups and solubility of muscle protein was accompanied by a loss of tenderness and development of dryness in frozen stored meat, while the amount of protein-breakdown products increased with the development of off-odour in meat stored either frozen or unfrozen.

Since both biochemical and quality changes depend on storage time and temperature, the possibility of employing the biochemical changes as an index of quality in stored poultry was considered. This communication presents evidence that the ratio between the -SH groups of muscle tissue, which indicate the degree of denaturation of muscle proteins, and protein-breakdown products, which indicate the degree of proteolysis, may be useful as a quality index for poultry stored frozen or unfrozen and for cooked frozen poultry. Separation and fractionation of myofibrillar proteins are lengthy procedures and cannot be used for routine quality control work, but simple analytical methods can be used to measure these parameters.

Samples of meat were obtained from male broiler-type chickens. The birds were killed in the laboratory by cutting the jugular vein and carotid arteries. They were bled for 2-3 min, scalded for 2 min at 53°-54° C, plucked by hand, eviscerated and aged for 48 h in drained, crushed ice. For frozen storage, birds were vacuum packaged in 'Cry-O-Vac' bags, frozen in an air blast (300-500 ft./min) at -30° C, stored at -18 and -10° C for the desired length of time (up to 2 years), and thawed for 2 h in running water at 18°-22° C. For storage at 0° C, birds were dipped in chlortetracycline solution (10 p.p.m.), placed in sterilized 'Cry-O-Vac' bags, flushed with nitrogen and stored under aseptic conditions for maximum storage life (up to 5 weeks). For pre-cooked frozen storage, the birds were vacuum packaged in 'Visking' bags, heated for about 3 h in boiling water to bring the internal temperature to about 85° C and stored at -10° C (up to 2 years) under nitrogen to minimize oxidation.

For analysis, breast and leg muscle were removed separately, freed from visible fat, tendon and connect tissues and minced with scissors. Minced tissue (5 g) was homogenized with sodium chloride (3 g), sand (3 g) and metaphosphoric acid (2.25 per cent, 20 ml.). The mixt was shaken, left for 5 min and filtered (Whatman No. 4). These operations were performed at 0° C on duplicate samples. The filtrate was used to estimate both -SH groups and protein-breakdown products. Sulphydryl groups were estimated in 2-4 ml. of filtrate by a colorimetric method using sodium nitroprusside reagent⁴ expressed as μg glutathione-SH per g muscle. For estimation of protein-breakdown products, 5 ml. filtrate was treated with 5 ml. 20 per cent trichloroacetic acid solution, allowed to stand at room temperature for 1 h and centrifuged for 10 min at 12,000 g . Protein breakdown products were estimated with Folin-Ciocalteu reagent⁵ 4 ml. supernatant^{1,2} and expressed as μg of tyrosine nitrogen per g muscle.

The ratio of -SH groups and tyrosine nitrogen content (suggested quality index) of both breast and leg muscle tissue decreased progressively with storage time in raw meat stored at temperatures above and below freezing and in cooked frozen meat (Fig. 1). During frozen storage the 'quality index' decreased as a result of loss of -SH groups and an increased proteolysis. During storage at 0° C for 5 weeks, changes in -SH group content of muscle tissue were small, and the 'quality index' decreased mainly as a result of proteolysis. In cooked meat in which proteolysis occurred, the 'quality index' decreased as a result of loss of -SH group content during frozen storage. The rate of decrease of 'quality index' increased rapidly with storage temperature in much the same way as the rate of quality deterioration increased in studies with uncooked meat^{5,6}. In muscle of birds from a single flock, killed, processed, and stored under identical conditions in the laboratory, the 'quality index' varied within ± 10 per cent.

The determination of the suggested objective 'quality index' should be much simpler, more accurate and reliable than the assessment of quality by sensory testing. The results may, therefore, be of interest in laboratory studies on the effect of freezing and storage procedures on poultry quality as well as in commercial freezing and storage of poultry. The effects of biological variability and processing techniques on the 'quality index' are being investigated.

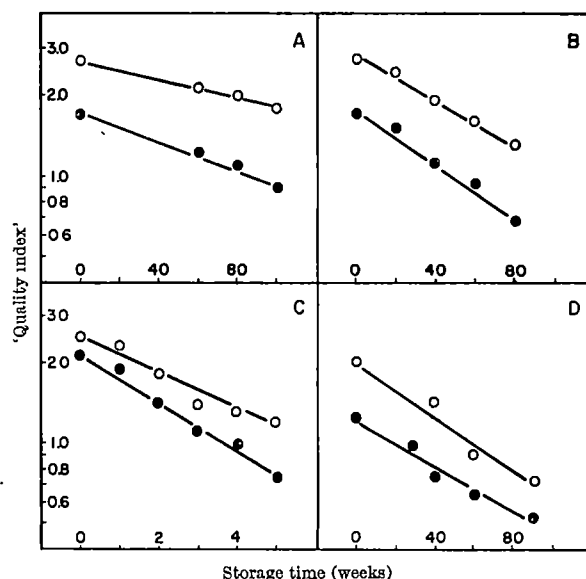

Fig. 1. Effect of storage time on suggested quality index (ratio between -SH group content and Folin-Ciocalteu reagent-positive nitrogen content of muscle tissue, plotted logarithmically). ●, Breast muscle; ○, leg muscle. A, raw poultry stored at -18° C; B, raw poultry stored at -10° C; C, raw poultry stored at 0° C; and D, cooked poultry stored at -10° C.

sed, and values of the 'quality index' corresponding to quality of meat when deterioration is first detected by sensory evaluation are being studied.

ANTHROPOLOGY

Lower Palaeolithic Hominid and Pebble-industry in Hungary

In the neighbourhood of the village of Vértesszöllös, to the north-west of Budapest, a rich Lower Palaeolithic site has been found: the results of the first excavation have already been published¹.

In 1964 a great part of the site was excavated, and this resulted in some new finds, which included a rich fauna as well as several thousand primitive pebble-tools.

The pebble-industry in Hungary, called *Buda-industry*, related to the Oldowan industry in Africa, the Moukoutienian in China, the Sohan in India and to the Tactonian in England so far as implement-types is concerned. The most characteristic forms are pebble-choppers, chopping-tools and polyhedrons. On the basis of its well-determinable stratigraphical conditions (the ravertine complex bearing the finds is situated on a high, old—possibly fourth—Pleistocene terrace) and of the rich vertebrate fauna, it was possible to compare our site with the Upper Biharian (that is, Mindel 1/2 and Mindel 2).

During the 1964 excavations four separate cultural horizons were found. The two lower ones were in solid ravertine and in lime-mud, while the upper two were at the base and at the top of the overlying loess. The loess again was covered with another layer of ravertine several metres thick. It was the lowermost layer which yielded the richest material; this represented a continuous living surface at the base of a former tectarata (calcareous tuff oasis). The material consists of numerous broken bones, and some small hearth, stones and chips. Of the three upper layers, that at the base of the loess was almost as rich in material as the lowest layer, but it covered a smaller area. The tools—so far as can be stated after a preliminary investigation—do not show any noticeable changes at the different cultural horizons. However, the fauna shows a considerable change: the vertebrate (rodent) material found in the loess belongs to cold-enduring species while those in the lower layers belong to a warmer climate: in the upper layer, beside the northern type red vole (*Myodes* [= *Clethrionomys*] cf. *rutillus*), there are *Microtus*-species and *Ochotona*, etc., in great abundance, thus indicating a cold climate. On the other hand, in the lower layers, Murines (*Apodemus*, *Mus*), *Cricetus* and *Glis* accompanied by *Phomys* (dying out later), and Microtines, which belong to a relatively warmer climate, indicate more temperate climatic conditions.

During the excavation, several hundredweights of lime-mud from the cultural layer were washed out and sieved, and taken to the Hungarian National Museum for preparation. The washing process and the collecting from the washed material took several months. It is for this reason that the most significant find of the excavation only came to light early in 1965: namely, tooth-remains of a hominid from the washed material of the lowest cultural horizon. The hominid remains consist of a left deciduous canine, the fragment of a first deciduous molar and fragments of another molar belonging to a

child's jaw. Even at first glance it was obvious that the teeth are characteristic of the *Pithecanthropus-Sinanthropus* group. Dr. A. Thoma has been asked to undertake detailed examination.

From the washed material where the human teeth were contained, the following mammalian species were also determined (there are only one or two new species in this list as compared with that already published): *Citellus* sp. (*citellus*-group), *Cricetus cricetus* ssp., *Myodes* [= *Clethrionomys*] cf. *glareolus* (*Schreber*), *Phomys* sp., *Arvicola* sp., *Phaiomys* sp., *Microtus* (*Pitymys*) *arvaldens* (Kretzoi), *Microtus conjungens* Kretzoi, *Microtus arvalis-agrestis*-group, *Apodemus* sp. (*szilaticus*-group).

The decreasing numbers, from the base upwards, of the *Pitymys arvaldens* and the greatly increasing numbers of the *Microtus conjungens*—an intermediate form between *Microtus hintori-gregaloides* and *Microtus gregalis*—are a clear indication of a deteriorating climate during the laying down of the upper layers of the site.

Cranial Capacity of the Hominine from Olduvai Bed I

PROF. P. V. TOBIAS¹ has produced a range of values for the cranial capacity of the 'pre-*Zinjanthropus*' juvenile from Bed I, at the F.L.K.N.N. I site at Olduvai Gorge, Tanganyika. This communication presents evidence which confirms Tobias's calculations.

The figures which Tobias calculated on the basis of his 'B/A' ratio, the parietal-to-total volume, were 642.7–723.6 c.c. These figures and the method of obtaining them have been criticized², and it is generally held that his figures are questionable. The main reason for this unwillingness to accept Tobias's figures rests with his method of reconstruction of a partial endocranion from the parietal fragments. Pilbeam and Simons² hold that the articulation of the parietals along the sagittal suture would make a considerable difference in the parietal volume, since a more acute angle of articulation along the suture would reduce the width at the base, thereby decreasing the volume.

Since the fragments are from both sides of the cranium, accurate reconstruction is possible by mirroring one side with the other. Thus, the reconstruction should be reasonably correct, disregarding for the present the question of articulation. Assuming also that the range of values found for partial endocranions, parietal-to-total, is within the values obtained (50.22–56.54 per cent), the question of articulation requires consideration.

Using the photographs and scale provided by Tobias¹, a full-scale drawing was made of the endocranion both as seen from above and behind. Using the maximal breadth and height as a plane, a template was constructed of the outline of the endocranion in this plane, from one side. By simply turning the template over, the mirror image could be traced. Using the most superior point in the mid-sagittal plane as a pivot point, the template was rotated a number of times, and outlines traced on fine-quality tracing paper. A 'reference' outline was made to conform with the scale of the published photograph. The maximum breadth in the coronal plane was varied from the 'reference' value in both directions. In other words, the angle of articulation at the sagittal suture was made both more and less acute. Each outline was traced, giving a total of four complete outlines: (1) at scale; (2) minus 0.5 cm each side; (3) minus 1.0 cm each side; (4) plus 0.5 cm each side. Thus, maximum breadth was varied from plus 1.0 cm to minus 2.0 cm, a range surely greater than necessary.

A planimeter was then used to obtain the areas enclosed by each of the four outlines, five readings being

taken for each outline. Each was then calculated in terms of the percentage of the 'reference' or scale area. The values resulting are as follows (per cent): (1) 'scale', 100; (2) minus 0.5 cm, 98.3; (3) minus 1.0 cm, 95.9; (4) plus 0.5 cm, 101.

It is immediately apparent that variations in the articulation angle along the suture do not radically reduce volume estimates. In varying the articulation angle, the decrease essentially affects but one dimension, that is, the lateral breadth. At the same time, the vertical dimension is increased. Since the shift is in one direction, it can be seen that by taking some small volume in the coronal plane, $A(dx)$ and integrating from anterior to posterior dimensions, one is essentially adding small volumes until total parietal volume results. What the planimeter method shows is that the loss in area from constriction of the breadth is almost compensated by the increase in depth. The area remains essentially constant, and since the length of the endocast is not affected by constriction the volume remains essentially constant also. It should be appreciated, however, that this method can only give an approximation, since the articulation in question is along a curved surface. If the entire suture were present in the fragments, it would not be possible to vary greatly the angle of articulation. Since the fragments are partial in this respect, some degree of freedom is allowed for articulation, and taking the area of but one plane of coronal orientation at the point of greatest depth would be roughly representative of a series of areas in different coronal planes.

In sum, Tobias's¹ values are probably correct, provided that: (1) the reconstruction is valid; (2) the partial endocast variation, 'B/A' ratio, is within the limits obtained.

It must be added, however, that this confirmation of Tobias's figures should in no way be taken as supporting his conclusions regarding the creation of a new species of early hominid. The parameter of cranial capacity is quite variable in the higher primates. The end-points of the greater than 1,000 c.c. variation between members of modern *Homo* are not placed in separate species, nor are gorillas, the volumes of which vary between 752 c.c. and 320 c.c. (ref. 3). Thus, it would not be unlikely that on the basis of cranial capacity, at least, the 'pre-Zinj' materials are within the Australopithecine taxon of early hominids.

RALPH L. HOLLOWAY, JUN.

Department of Anthropology,
Columbia University, New York.

¹ Tobias, P. V., *Nature*, 202, 3 (1964).

² Pilbeam, D. R., and Simons, E. L., *American Sci.*, 53, 237 (1965).

³ Schultz, A. H., *Anthropol. Anz.*, 25, 197 (1962).

PROF. HOLLOWAY has shown effectively that the partial endocast of *Homo habilis* provides a valid basis for estimating its cranial capacity, and even for a far greater range of angles along the sagittal suture than are anatomically likely. He has increased the maximum (biasterionic) breadth by as much as 10 mm and reduced it by as much as 20 mm and found a minimal effect on the cross-sectional area of the biparietal tunnel. It is of interest that the difference in biasterionic breadth between two reconstructions made in Nairobi and in Johannesburg was scarcely 2 mm. The first was made by Dr. L. S. B. Leakey and myself, with the auxiliary observational judgment of Dr. G. G. Simpson, Mrs. M. Leakey and Mrs. S. Coryndon; the second was made by A. R. Hughes and myself. The tolerance limits of our reconstructions were 2 mm; Prof. Holloway has validated the method for a range of 30 mm between the greatest and smallest biasterionic distances!

Two comments may be added on variability in higher primates:

(1) The capacity of 680 c.c. in *H. habilis* exceeds the australopithecine mean of 502 c.c. ($n=7$) by 3.79 standard

deviations. (The *S.D.* of 47.0 c.c. is an estimate of *t* population *S.D.*, based on an australopithecine sample range of 435–562 c.c. For this calculation, the adult capacity of the Taung fossil was re-computed from the newer growth data of Ashton and Spence², which show that, by the dental age of the Taung child, the cranial capacities of hominoids have reached 90–94 per cent the adult mean values. The proposed new 'adult' value for Taung of 562 c.c. replaces the 600 c.c. I formerly accepted³. Even on the former estimate, however, 680 c.c. was 3 *S.D.*'s higher than the australopithecine mean.)

(2) It is extremely hazardous to apply to a fossil group such as *Australopithecus* the *a priori* argument that variability must have been at least of the order four in living higher primates. There is much evidence that the variability of metrical characters may vary from taxon to taxon; thus, for cranial capacity, the coefficient of variation may be as low as 6.8 in chimpanzee and as high as 13.6 in gorilla ($\sigma+\varphi$), or 12.8 in modern man. Even if we separate male and female gorilla capacities, the gorilla male *V* of 10.4 is higher than that of orang-utans or chimpanzees for both sexes combined! Many factors enhance the variance and these may not operate equally in different hominoids, for example, varying degrees of sexual dimorphism, the possible effect of zoo conditions on higher primates and the proportions of zoo-reared and wild-shot animals represented in a skeletal series, the degree of polytypism and polymorphism within a taxon etc.

Not only may a single metrical character vary to different degrees from population to population, but also different taxa may show high or low overall variability. Morant⁴ proved that, in contrast with modern man, Neanderthal man was remarkably homogeneous in cranial metric characters. This was stressed again not long ago by Blanc, by Vallois and by Caspari⁵, the latter adding that "in recent man interindividual variability appears to be relatively large as compared with a number of other species". The Biometric School produced many investigations which showed wide diversity of variability among different human populations and different great apes.

We simply do not know if *Australopithecus* was a highly variable taxon in general, or whether cranial capacity in this group was of low or high variability. The estimated coefficient of variation based on the present australopithecine sample of 7 cranial capacities is 9.35 per cent which is higher than that of smaller-brained apes, but lower than that of gorilla and modern man. But the problems intrinsic in palaeontological sampling make it very likely that this is an imperfect estimate. Further specimens of australopithecines may place the value of 680 c.c. well within the mean ± 3 *S.D.*'s; but we cannot assume that this will be so, nor can we base statements on the possible features of specimens still to be discovered. On the existing sample, the estimated cranial capacity of *H. habilis* is significantly greater than the mean australopithecine capacity.

Note added in proof. Dr. J. K. Woo⁶ has meanwhile applied my method to his important new pithecanthropine cranium from Lantian, Shensi Province. From a biparietal reconstruction and endocast, he has obtained estimates of the total endocast volume of 775–783 c.c. Using one of Pearson's formulae on the complete reconstructed cranium, he has obtained a value of 778 c.c. These remarkably similar estimates agree with Woo's total morphological assessment in aligning the Lantian specimen with the small-brained Indonesian crania of *Homo erectus*.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, October 11

- INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (Joint Conference with the Schools Council, at 1 Birdcage Walk, Westminster, London, S.W.1), at 2.30 p.m.—Conference on "Applied Science Engineering Activities in Schools".
- SOCIETY OF CHEMICAL INDUSTRY, COLLOID AND SURFACE CHEMISTRY GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. B. W. Wilson: "Surface-Active Agents in the Pharmaceutical Field".
- UNIVERSITY OF LONDON (in the Botany Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. G. Drews (University of Freiburg): "The Cell of the Photosynthetic Bacteria in Light- and Dark-Metabolism" (further lecture on October 13).
- ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"Germany: a Regional Geography" (colour film).

Tuesday, October 12

- UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. H. E. Lewis: "The Islanders of Tristan da Cunha—a Medical Study of Isolation".
- ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.
- INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. E. M. Wilson: "A Study of the Feasibility of Tidal Power from Loughs Strangford and Carlingford with Pumped Storage at Rostrevor".
- INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Annual Meeting. 10 p.m.—Mr. R. S. Moul: "An Engine Designer's Scrapbook" (Chairman's address).

Wednesday, October 13

- SCHOOL OF PHARMACY, UNIVERSITY OF LONDON (in the Assembly Hall, 21 Tavistock Square, London, W.C.1), at 3 p.m.—The Lord Brain, Bt., D.M., R.C.P., F.R.S.: "Drug Dependence".
- ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5 p.m.—Mr. M. Hills: "Allocation Rules and Their Error Rates".
- INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (at 9 Bedford Square, London, W.C.1), at 6 p.m.—Dr. D. C. Cooper: "Signal Processing Using Optical Techniques".
- SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Meeting on "The Future of Food Legislation". Mr. D. D. Moor: "The Public Analyst's View"; Dr. A. M. Taylor: "The Viewpoint of the Manufacturer".
- INSTITUTE OF SCIENCE TECHNOLOGY, LONDON BRANCH (in the Electrical Engineering Department, Imperial College, Exhibition Road, London, S.W.7), at 6.30 p.m.—Prof. C. Cherry: "The Communication Explosion".

Thursday, October 14

- INSTITUTE OF PETROLEUM, ECONOMICS AND OPERATIONS GROUPS (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. R. Marsh: "The Industrial Training Act".
- INSTITUTION OF CIVIL ENGINEERS, TRANSPORTATION ENGINEERING GROUP (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Formal Discussion on "Motorist's View of Road Problems", introduced by Mr. E. Shipley.
- INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Avoy Place, London, W.C.2), at 5.30 p.m.—Mr. L. E. S. Mathias: "Long Wavelength Laser Generation".
- INSTITUTION OF MECHANICAL ENGINEERS, HYDRAULIC PLANT AND MACHINERY GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Dirt in Fluid Power Systems—Should it be Excluded or Tolerated?"

Friday, October 15

- ARTHUR STANLEY EDDINGTON MEMORIAL TRUST (in Room 3, Mill Lane Lecture Rooms, The University, Cambridge), at 5 p.m.—Sir John C. Eccles, F.R.S.: "The Brain and the Unity of Conscious Experience" (1965 Eddington Memorial Lecture).
- INSTITUTION OF MECHANICAL ENGINEERS, THERMODYNAMICS AND FLUID MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Discussion on "Flow Visualization".

Saturday, October 16

- INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. John Okell: "Burmese Musical Instruments".

Monday, October 18

- PLASTICS INSTITUTE, PLASTICS PROPERTIES DISCUSSION CIRCLE (at the Mandeville Hotel, Mandeville Place, London, W.1), at 3 p.m.—Mr. D. A. Hill: "Impact Testing and Brittle Failure".
- UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Prof. B. A. D. Stocker: "Salmonella Antigens—Structure and Genetics" (further lecture on October 25).
- BRITISH COAL UTILIZATION RESEARCH ASSOCIATION (in the Lecture Theatre, Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Prof. D. B. Spalding: "Heat Transfer Aspects of Coal Utilization" (Fourteenth Coal Science Lecture).
- SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. J. H. Hamence: "The Public Analyst's Approach to Pesticide Residues".

INSTITUTION OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINES GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Whither Small V-Torn Diesel Engines?"

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Dr. Charles Swithinbank: "A Year with the Russians in Antarctica".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

POSTDOCTORAL FELLOW (cell biologist or biochemist) IN THE DEPARTMENT OF ZOOLOGY to work with Dr. L. G. E. Bell on problems associated with cell surface function—The Deputy Secretary, The University, Southampton (October 12).

LECTURER (with a good honours degree in a science subject and preferably experience of teaching chemistry in secondary schools; a knowledge of Welsh will be an additional qualification) IN EDUCATION—The Registrar, University College of North Wales, Bangor, North Wales (October 14).

LECTURERS (with a good honours degree and a keen interest in any branch of electronics and control engineering) IN THE ELECTRONICS AND CONTROL DIVISION, School of Engineering Science—The Registrar, University College of North Wales, Bangor, North Wales (October 14).

ASSISTANT LECTURER or LECTURER (preferably with a special interest in analysis) IN PURE MATHEMATICS—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (October 18).

LECTURER IN METALLURGY—The Principal, Lanchester College of Technology, Priory Street, Coventry (October 18).

ASSISTANT LECTURER (with a wide interest in genetics so as to be able to lecture to students of both departments) IN GENETICS IN THE DEPARTMENTS OF BOTANY AND ZOOLOGY—The Registrar, The University, Manchester, 13, quoting Ref. 174/65/Na (October 20).

LECTURER (Grade II) IN THEORETICAL CHEMISTRY—The Registrar, University Senate House, Bristol, 2 (October 20).

LECTURER or ASSISTANT LECTURER (with research experience in any branch of computer science and preferably an interest in programming languages, systems programming or non-numerical applications of computers) IN THE COMPUTATION LABORATORY, DEPARTMENT OF MATHEMATICS—The Deputy Secretary, The University, Southampton (October 22).

RESEARCH FELLOW (with a first- or second-class honours degree, and preferably ecological training and previous research experience) IN THE DEPARTMENT OF ZOOLOGY, to work on the general ecology of the fox for a period of three years—The Secretary, The University, Aberdeen (October 23).

SENIOR LABORATORY ADMINISTRATOR (with previous administrative experience, and preferably laboratory or medical knowledge) IN THE DEPARTMENT OF ANATOMY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (October 23).

CHAIR OF MATHEMATICS and HEAD OF THE DEPARTMENT OF MATHEMATICS—The Academic Registrar, Northampton College of Advanced Technology, St. John Street, London, E.C.1 (October 25).

CHAIR OF NUMERICAL ANALYSIS—The Registrar, University of Strathclyde, Glasgow, C.1 (October 25).

LECTURERS IN NUMERICAL ANALYSIS; LECTURERS IN STATISTICS; and a LECTURER and an ASSISTANT LECTURER IN PURE MATHEMATICS—The Registrar, University of Strathclyde, Glasgow, C.1 (October 25).

RESEARCH ASSISTANT (male or female honours graduate in any of the biological sciences, including medicine, interested in animal cell biology, and preferably laboratory experience in culture techniques) IN TISSUE CULTURE IN THE DEPARTMENT OF ANATOMY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (October 25).

WELLCOME CHAIR OF PHARMACOLOGY at the SCHOOL OF PHARMACY—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 28).

SENIOR LECTURER IN PHYSICS and THEORETICAL PHYSICS; a SENIOR LECTURER IN HIGHWAY ENGINEERING; a SENIOR LECTURER/LECTURER IN ANTHROPOLOGY; a LECTURER or SENIOR LECTURER IN GEOPHYSICS, a LECTURER IN MICROBIOLOGY; and a SENIOR DEMONSTRATOR/DEMONSTRATOR IN ANTHROPOLOGY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, October 29).

SENIOR LECTURERS or LECTURERS (3) IN GEOLOGY at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 29).

ASSISTANT CURATOR (with field experience in ethnology) OF THE MUSEUM OF ARCHAEOLOGY AND ETHNOLOGY—The Secretary of the Appointments Committee, Faculty of Archaeology and Anthropology, University of Cambridge, Downing Street, Cambridge (October 30).

CHAIR OF BOTANY—The Deputy Secretary, The University, Southampton (October 30).

EXPERIMENTAL OFFICER (young graduate interested in the design and construction of electronic and electro-acoustic equipment) IN THE DEPARTMENT OF AUDIOLOGY and EDUCATION OF THE DEAF—The Registrar, The University, Manchester, 13, quoting Ref. 179/65/Na (October 30).

LECTURER IN THE DEPARTMENT OF PHARMACOLOGY—The Clerk to the Council, School of Pharmacy, University of London, 29/39 Brunswick Square, London, W.C.1 (October 30).

LECTURER IN BIOCHEMISTRY—The Registrar, King's College (University of London), Strand, London, W.C.2 (October 31).

SENIOR LECTURER or LECTURER IN AGRICULTURAL ENGINEERING at the University of Khartoum—The Registrar, University of Khartoum, c/o The Inter-University Council, 33 Bedford Place, London, W.C.1 (October 31).

LECTURER (preferably with experience in comparative and cellular physiology) IN THE DEPARTMENT OF ZOOLOGY, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (November 1).

RESEARCH STUDENT IN METALLURGY for work concerned with the mass-transfer of alloying elements, especially carbon, between plain carbon and alloy steels, immersed in high purity molten sodium at temperatures up to 850 deg. C.—The Registrar, King's College (University of London), Strand, London, W.C.2 (November 1).

CHAIR OF PLANT SCIENCE; and LECTURERS IN BIOLOGICAL SCIENCE at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 4).

DEPARTMENTAL ADMINISTRATOR IN THE DEPARTMENT OF CHEMISTRY—The Deputy Secretary, The University, Southampton (November 6).

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

SENIOR LECTURER or LECTURER (medically qualified with adequate experience) in the DEPARTMENT of CHEMICAL PATHOLOGY, University of Ibadan, Nigeria—The Secretary, Senate Committee on Higher Education Overseas, University of London, Senate House, London, W.C.1 (November 8).

SENIOR LECTURER or LECTURER (chemical engineer, preferably with industrial experience of process control) in CHEMICAL PROCESS CONTROL in THE DEPARTMENT of SYSTEMS ENGINEERING—The Secretary, University of Lancaster, Bailrigg House, Lancaster (November 13).

PRINCIPAL of THE WEST of SCOTLAND AGRICULTURAL COLLEGE and PROFESSOR of AGRICULTURE in the University of Glasgow (combined appointment)—The Principal, The West of Scotland Agricultural College, 6, Blythswood Square, Glasgow, G.2 (November 15).

POST-DOCTORAL FELLOW (chemist, biologist or physicist with experience in electron microscopy, with a Ph.D. degree or postgraduate research experience of equivalent standard and duration supported by satisfactory evidence of research ability) in ELECTRON MICROSCOPY in THE DIVISION of PROTEIN CHEMISTRY, Commonwealth Scientific and Industrial Research Organization, Parkville, Melbourne—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 462/236 (November 20).

ASSISTANT BACTERIOLOGIST (preferably female, with a university degree and/or practical experience in food microbiology)—The Director, Research Station, The Fruit and Vegetable Canning and Quick Freezing Research Association, Chipping Campden, Glos.

ASSISTANT LECTURER or LECTURER (with research interests in nuclear magnetic resonance spectroscopy) in ORGANIC CHEMISTRY—Prof D. H. R. Barton, F.R.S., Department of Chemistry, Imperial College of Science and Technology, London, S.W.7.

ASSISTANT LECTURER (with appropriate qualifications in biology, mycology or botany, and preferably special qualifications in plant mycology or general mycology) in BIOLOGY—The Registrar, University of Strathclyde, Glasgow, G.1.

CHEMISTRY MASTER (well qualified) to teach up to advanced level—The Headmaster, Latymer Upper School, Hammersmith, London, W.6.

DEMONSTRATOR (honours B.Sc. biochemistry or chemistry) to ASSIST in LABORATORY and TUTORIAL INSTRUCTION in THE DEPARTMENT of BIOCHEMISTRY—The Secretary, Royal Free Hospital, School of Medicine (University of London), Hunter Street, London, W.C.1.

ELECTRON MICROSCOPE TECHNICIAN (with experience in biological and physical work and a sound knowledge of replica, embedding and sectioning techniques) to take charge of the operation and maintenance of a Siemens Elmiskop MKI and ancillary equipment—The Director of Research, Natural Rubber Producers' Research Association, 56 Tewin Road, Welwyn Garden City, Herts.

ENTOMOLOGIST (with a B.Sc. degree with honours in zoology or entomology, and preferably practical experience of control of field pests and pests of stored products) in British Honduras, to advise the Agricultural Extension Staff and farmers on pest control measures, to evaluate insecticides and undertake basic field research in pest control, to lecture on pests and pest control and to advise on legislation to control the use of certain insecticides, and pest control generally—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RG 213/26/03.

EXPERIMENTAL OFFICER to work on electronic instrumentation in the field of cardiology—The House Governor, Charing Cross Hospital, London, W.C.2.

HEAD of THE NEW ZEALAND SCHOOL of PHARMACY, Central Institute of Technology—The High Commissioner for New Zealand, New Zealand House, Haymarket, London, S.W.1, or The Director of Education, Private Bag, Wellington, New Zealand.

MICROANALYST (with experience in micro-elementary and functional group analysis, and preferably familiarity with the operation and maintenance of electronic equipment) in THE ORGANIC CHEMISTRY DIVISION of the National Chemical Research Laboratory, O.S.I.R., South Africa, to take charge of the routine microanalytical operations of the laboratory—The South African Scientific Liaison Officer, Chichester House, 278 High Holborn, London, W.C.1.

POST-DOCTORAL ASSISTANT; and a TECHNICAL ASSISTANT in INORGANIC CHEMISTRY to work under the supervision of Dr. J. F. Nixon—The Secretary, Department of Chemistry, St. Salvator's College, University of St. Andrews, St. Andrews, Fife, Scotland.

PRINCIPAL GRADE BIOCHEMIST (with a higher degree in chemistry or biochemistry)—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Ref. No. P/836.

RESEARCH ASSISTANT (preferably with a degree in botany, agriculture, agricultural botany or other equivalent qualification) in THE POTATO BRANCH for work on herbicides in relation to potato varieties—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

RESEARCH ASSISTANT (zoology graduate) in THE DEPARTMENT of ZOOLOGY and APPLIED ENTOMOLOGY, Imperial College of Science and Technology, to work at the College Field Station, Silwood Park, on chemical factors in host plant selection by phytophagous insects or on the reproductive behaviour of insects—Dr. C. T. Lewis, Silwood Park, Sunninghill, Ascot, Berks.

RESEARCH ASSISTANTS (with a degree in chemistry or equivalent and preferably interested in the kinetics of exchange reactions) in RADIOCHEMICAL STUDIES—The Senior Lecturer in Radiochemistry, Sir John Cass College, Jewry Street, London, E.C.3.

RESEARCH ASSISTANTS (with a good degree in physics or electrical engineering) for work on resonances excited by microwaves in the plasma of a discharge column and on the application of these resonances in the field of electronics—Prof. M. Potok, Royal Military College of Science, Shrivenham, near Swindon, Wiltshire.

RESEARCH ASSISTANTS (2) (with qualifications in engineering or physics and preferably some experience in research) in THE DEPARTMENT of MECHANICAL ENGINEERING, for work in the fields of (a) hydrodynamic lubrication, and (b) fluid control systems—The Registrar, The University, Sheffield, 10.

SENIOR TECHNICIAN in THE DEPARTMENT of CHEMICAL PATHOLOGY to assist in the investigation of sick children—The Chemical Pathologist, Hospital for Sick Children, Institute of Child Health, Great Ormond Street, London, W.C.1.

SENIOR TECHNICIAN (preferably with previous experience with polymer equipment) for the maintenance and operation of modern equipment in a polymer characterization laboratory—The Departmental Superintendent, Chemistry Department, Imperial College, London, S.W.7.

SENIOR TECHNICIAN (with H.N.C. or equivalent qualification in physics, chemistry or biology, and preferably experience in physical instrumentation and an interest in field work) in THE ECOLOGY SECTION of THE DEPARTMENT of FORESTRY—Dr. M. E. D. Poore, Department of Forestry, Forestry Institute, University of Oxford, Oxford.

Bulletin of the British Museum (Natural History). Entomology. Vol. No. 2: A Systematic Revision of the Ameninidae (Diptera: Calliphoridae) By R. W. Crosskey. Pp. 33-140 35s. Vol. 16, No. 3: A Revision of Nodini and a Key to the Genera of Eumolpidae of Africa (Coleoptera: Eumolpidae). By B. J. Selman Pp. 141-174. 14s. (London: British Museum (Natural History), 1965)

Water Resources Board. Logarithmic Plotting of Stage-discharge Observations. By A. I. G. S. Robertson. Pp. 36. (T.N.3.) Origin published 1962. (Reading: Water Resources Board, 1965.)

Philosophical Transactions of The Royal Society of London. Series Biological Sciences. No. 758, Vol. 249 (28 August, 1965). A Submer Late-quaternary Deposit at Roddars Port on the North-East Coast Ireland. By M. E. S. Morrison and N. Stephens. (With Appendices Mrs Margaret Jope and S. P. Dance, F. W. Anderson, F. E. Round, H. Godwin, and E. H. Willis.) Pp. 221-225. (London: The Royal Society, 1965.) 18s.; 2.70 dollars.

University of Bristol. Annual Report of the Long Ashton Agricultural and Horticultural Research Station (The National Fruit and Cider Institute for the year 1964). Pp. xi+229+5 plates. (Long Ashton: The Agricultural and Horticultural Research Station, 1965.) 15s.

Fourth Report from the Select Committee on Procedure, together with Proceedings of the Committee Relating to the Report, Minutes of Evidence and Appendices, Session 1964-65. Pp. xxiii+148. (London: H. Stationery Office, 1965.) 15s. net.

Other Countries

Republic of Zambia. Ministry of Lands and Natural Resources. Annual Report of the Department of Water Affairs for the year 1964 Pp. (Lusaka: Government Printer, 1965.) 2s.

The Vegetation of Uganda and its Bearing on Land-use. By I. Langds Brown, H. A. Osmaston and J. G. Wilson. Pp. 159+24 plates. (Entebbe: Government Printer; London: The Uganda High Commission, 1965) 30/-

Académie Royale de Belgique. Classe des Sciences—Mémoires. Tome 1: Fascicule 1: On the Summability Methods of Divergent Series. By Kan Ishiguro. Pp. 43. 60 francs. Tome 35, Fascicule 3: Schistosité et Granitisation dans le Synchronisme de Laval et ses Abords. Par Paul Fourmarier, Annik Palhate et Bernard Auvray. Pp. 60. 140 francs. Tome 35, Fascicule 4b: Étude Expérimentale et Interprétation du Spectre Infra-Rouge des Silicates et des Germanates. Application à des Problèmes Structuraux Relatifs à l'état Solide. Fascicule 1: Pp. 261. Fascicule 2: Pp. 134 (164 fig 540 francs. (Bruxelles: Académie Royale de Belgique, 1965.)

Records of the Australian Museum. Vol. 26, No. 7 (12th June, 1965). Soil and Landscape History in the Vicinity of Archaeological Sites at Gl. Davis, New South Wales. By P. H. Walker. Pp. 247-264+plates 25-27. (Vol. 26, No. 8 (19th June, 1964): Notes on the Genera *Amoria* Gray, 18 and *Zebromoria* Iredale, 1924 (Gastropoda: Volutidae), with Descriptions New Species. By Donald F. McMichael. Pp. 265-274+plate 28. 3s. Vol. 2 No. 9 (28th June, 1964): Rediscovery of the Echinoderm *Clypeaster tumid* (Tenson-Woods) and an Amended Description. By R. Endeian and Elizabeth Pope. Pp. 275-281+plates 29 and 30. 2s. 6d. Vol. 26, No. 10 (17th July 1964): New Linguloid Shells from Lower Ordovician and Middle Palaeozoic Rocks of New South Wales. By H. O. Fletcher. Pp. 289-294+plates 31 and 32. 4s. Vol. 26, No. 13 (30th December, 1964): Merostomolidae (Arthropod Trilobitomorpha) from the Australian Middle Triassic. By E. F. Riek. Pp. 327-332+plate 35. 2s. (Sydney: The Australian Museum, 1964.)

New Zealand Forest Service: Forest Research Institute. Research Note No. 41: Trials with Arboricides for Control of Coppice Growth of Indigenous Hardwoods. By A. E. Beveridge. Pp. 10. (Wellington: Government Printer, 1965)

Mutations in Quantitative Traits: Report on Symposium held on July 1 and 29, 1964. (Gamma Field Symposia, No. 3.) Pp. iii+150 (Ohmiya-machi Ibaraki-Ken, Japan: The Institute of Radiation Breeding, Ministry of Agriculture and Forestry, 1965)

Académie Royale de Belgique. Classe des Sciences—Mémoires. Tome 35, Fascicule 5: A Study of Molecular and Physical Processes in Comets. By D. Claude Arpigny. Pp. 157. (Bruxelles: Académie Royale de Belgique, 1965) 200 francs.

Western Australian Naturalists' Club. Handbook No. 8: Frogs of Southern Western Australia. By A. R. Main. Pp. 73 (5 plates). (Perth: Western Australian Naturalists' Club, 1965.) A6s.

National Hydatids Council, Wellington, New Zealand. Fifth Annual Report and Statement of Accounts for the year ended 31st March, 1965 Pp. 40. Information Bulletin No. 15: Hydatids Eradication in Iceland Pp. 11. Hydatid Disease in New Zealand: An Account of the Events leading to the Establishment of the National Hydatids Council, and the Method adopted to Eradicate the Disease. By F. S. Maclean. Pp. 48. Parasitic Animals with Special Reference to Hydatid Disease and Its Prevention. By R. M. Miller. (Reprinted from "Biology for Sixth Forms". Teach and Test Publications, Ltd., Otahuhu, New Zealand.) Pp. 36. (Wellington: The National Hydatids Council, 1965.)

Annals of the New York Academy of Sciences. Vol. 123, Article 2: Geotical Problems in Lunar Research. By J. E. M. Adler and 60 other authors Pp. 367-1257. (New York: New York Academy of Sciences, 1965.)

(Continued overleaf)

modern teaching depends on Unicam precision

Modern analytical techniques must be included in scientific education.

Yet students and precision instruments are often thought incompatible.

The Unicam SP600 is the ideal solution — a precision spectrophotometer of extremely robust design with time-tested components. Thousands of SP600's are in constant use throughout the world setting the standard for spectroscopic measurement in the range 360-1000m μ .

Send for full descriptive literature today.

Some of the eighteen Unicam SP600 Spectrophotometers in use in a Teaching Laboratory at the Department of Biochemistry, University of Cambridge, are illustrated on the left.

what do you do with data?

As makers of a range of rugged, reliable, economical and flexible Data and Instrumentation Recording equipment, we know a thousand and one ways of using magnetic recording for data acquisition, storage and analysis—in aeronautics, medicine, industry and university research work. Magnetic recording provides a wide range of band widths and high information packing density. Data expansion and contraction facilities are available which are not possessed by other forms of data acquisition. Thermionic equipment is the lowest priced range of digital and analogue recorders for research—we designed it on the unit principle for complete flexibility of use and we're sure it will answer your data handling problems.

You tell us!

Tell us what your particular research requirements are and we'll show you how THERMIONIC Data Recording Systems can meet them quickly, simply, cheaply. Drop a line to us today.

SCIENTIFIC AND TECHNOLOGICAL INFORMATION IN PARLIAMENT

At a meeting in June 1964, the Parliamentary and Scientific Committee agreed to set up a sub-committee, consisting of the Parliamentary members of its Steering Committee, to consider whether there was need for improved methods by which Members of Parliament could quickly obtain information from scientists about matters likely to be raised in Parliament. Moreover, the sub-committee was to consider what could be done to prove existing machinery to ensure that Parliament could establish more effective control over scientific and technological policy. For the purposes of this enquiry, the sub-committee co-opted Sir Harry Legge-Bourke and Dr. Jeremy Bray. An interim report entitled 'Parliament and Science', dealing solely with the means for ensuring more effective Parliamentary control over scientific and technological policy, has now been issued. This is included, together with a memorandum by Dr. Bray on 'Financial Procedure', as an appendix to the fourth report from the Select Committee on Procedure for the Session 1964-65*.

Although in the report from the Select Committee on Procedure this memorandum constitutes the chief interest of the scientist, it is not the sole feature of interest. The report as a whole and its four recommendations are of general interest, reflecting the critical problem of the mechanism of advice and informed discussion in general, but it may be as well to deal first with this report from the Parliamentary and Scientific Committee. Its sub-committee fully recognized that science and technology are both means and objects of policy, and that, besides their responsibility for implementing any policy adopted, experts could point out the probable effects of alternative choices. The sub-committee also recognized that, if Parliament decided to improve the present system of Parliamentary control of policy and administration in the scientific field, for example, by means of a 'select committee', it would have to define its order of reference so as to try to avoid becoming involved in policy decisions.

The sub-committee had before it a paper written by the chairman of the Parliamentary and Scientific Committee, Mr. Austen Albu, entitled "The Member of Parliament, the Executive and Scientific Policy", published in *Minerva* in 1963, to which reference has already been made in *Nature* (201, 955; 1964), as well as a pamphlet *Change or Decay* written by a group of Conservative Members of Parliament. However, the sub-committee decided to restrict itself to the means by which Parliament could be better informed on research and development in the civil field undertaken with public funds and in support of public policy. The considerations already noted led it to recommend the establishment of a select committee to examine, with the view of informing the House on their work and future, the annual reports of such bodies as the Research Councils, the Atomic Energy Authority, the National Research Development Corporation, and also the activities of scientific research groups and establishments in Government departments. It also recommended that this committee should, from time to time, make *ad hoc* enquiries into scientific and technological matters which

are under consideration as a basis for legislation or the formulation of policy.

The advantage of this proposal would be that Members of Parliament would hear something of the differing scientific and technical views which were under consideration in the department concerned. This would make for more informed debates and should also assist in differentiating technical from political issues. Admittedly reference to a select committee should be sparingly used, but the sub-committee hoped that a practice would develop of referring legislation involving scientific matters to this committee before or during its passage through Parliament. The sub-committee recommended that the select committee should consist of thirteen members (five to constitute a quorum), and that it should have the power to send for persons, papers and records. It did not consider that the select committee should be provided with expert staff but rather that experts should be called, when required, as witnesses. It was hoped that an expanded library and reference service, with scientific staff, would also be available to assist the proposed committee.

This latter point is strongly urged in a memorandum by the Study of Parliament Group, which is a private group of university teachers and officers of both Houses of Parliament which has been meeting since the summer of 1964, under the chairmanship of Sir Edward Fellowes, for the serious study of the working of Parliament. The memorandum concentrates on the procedure on public Bills and on the scrutiny and investigation of policy and administration; it emphasizes that Parliamentary scrutiny of the Executive is fundamental to the whole question of Parliamentary reform. The main task of the Government is to govern, and the main tasks of Parliament are to sustain the Government and to criticize its policies and actions.

The memorandum firmly asserts that Parliamentary control means influence, not direct power; advice, not command; criticism, not obstruction; scrutiny, not initiative; and publicity, not secrecy. The Group believes that strong government needs critical opposition; it can benefit from such criticism and stand up to it. Accordingly the Group suggests a greater degree of specialization by Members of Parliament and the Committees through which, increasingly, they should work. It is in this context that it points to the implications for the research and information services available to Parliament. Changes in and expansion of the services provided by the Library could be as important as any procedural changes in the basic task of creating or restoring adequate supervision by Parliament of the activities of Government. Present difficulties in this respect are, in the view of the Group, unlikely to be resolved unless Parliament is willing some time to look at the problem as a whole and consider how procedure, research and information, facilities and accommodation, form part of an integrated system so that changes in one, voluntary or involuntary, must lead to changes in others.

The essential aspect of any comprehensive proposal for enabling the House of Commons to perform its crucial role in scrutiny and investigation of policy and administration is the provision of adequate research and information facilities for both committees and individual Members.

* Fourth Report from the Select Committee on Procedure, together with the Proceedings of the Committee Relating to the Report, Minutes of Evidence and Appendices, Session 1964-65. Pp. xxiii + 148. (London: H.M.S.O., 1965.) 15s. net.

Only a properly developed Library with an expanded research department could provide access to the information necessary to Members for the informed discharge of their Parliamentary responsibilities, and the Group believes that the present research services of the Library could and should be improved. It has, in fact, prepared a report on the provision of research and information services which it hopes to submit to any committee established to consider this problem.

The Select Committee on Procedure did not, in the present report, pursue this question, but its four recommendations give substantial effect to the recommendations of the Parliamentary and Scientific Committee and to the proposals of the Study of Parliament Group for Specialist Committees of Advice and Scrutiny. Five such committees were suggested by the Group for initial experiment, covering scientific development; prevention and punishment of crime; machinery of national, regional and local government and administration; housing, building and land use; and the social services. The Select Committee on Procedure recommends the establishment, as a development of the present Estimates Committee, of a new select committee "to examine how the departments of State carry out their responsibilities and to consider their Estimates of Expenditure and Reports". The new committee should function through sub-committees specializing in the various spheres of Government activity and should be able to employ specialist assistance. There should be two clerks supervising the work of the Committee and one full-time clerk to each sub-committee. The power of select committees to adjourn from place to place should include the power to travel abroad, with the leave of the House, when investigations require it.

In making these recommendations, the Select Committee was obviously influenced by the experience gained with the Select Committee on the Nationalized Industries. It was also noticeably influenced by views expressed by the Estimates Committee, which is precluded by its terms of reference from investigating long-term proposals and prospects for expenditure in the various fields or from examining the administrative policy of Government departments apart from considerations of economy alone. It is not the wish of the Select Committee on Procedure that the specialist committees proposed should become involved in matters of political controversy. Certainly, it is well aware that it is not easy to distinguish between what are questions of policy and what are not, but it believes that the Select Committee on the Nationalized Industries has demonstrated what is possible in a field that is politically highly sensitive. The Committee was anxious also to retain the experience and method of work of the Estimates Committee, and for this reason recommended a series of sub-committees operating through a co-ordinating committee rather than a series of independent committees.

While the recommendations do not strictly follow those of the Parliamentary and Scientific Committee, running more on departmental lines than those of the Study of Parliament Group, it should still be possible for scientific matters to be examined in a context such as the examination of the annual reports of the Research Councils and other bodies would provide—as suggested by the former Committee. The idea of specialist committees has had powerful advocates in recent years, though Mr. Albu did not give it strong support in his paper on "The Member of Parliament, the Executive and Scientific Policy". The more limited proposal of the Parliamentary and Scientific Committee might yet

command wider support among those who recognize vital importance of informed discussion of scientific and technological matters in forming public policy. Curious enough, the recommendation drew no comment from Mr. Horace King in his statement before the Committee. However, he did affirm that he was one who thought that the power of the Executive was growing and ought to be diminished. For all that he wished to preserve, so far as possible, Parliament's historic and traditional features, he was concerned above all to promote its efficiency and would remove anything that impaired it.

Mr. Albu at least recognized the growing demand especially among younger Members, for a properly equipped research and information service, staffed with men and women who had been educated in a broad range of subjects, including the scientific and technological. The observations of the Study of Parliament Group on this point are among the most pertinent in the whole report and deserve further attention by the Parliamentary and Scientific Committee itself. Adequate library research and information services are indeed a key factor in informed discussion in Parliament. The Parliamentary and Scientific Committee should be able to do something to see that the observations of the Study Group, which includes such authorities as Prof. M. Beloff, Prof. J. Bromhead, Prof. A. H. Hansen, Prof. W. J. M. Mackenzie, Prof. W. A. Robson, Prof. H. Wiseman, Dr. D. N. Chest and Dr. B. Crick, are duly noted and that the committee suggested to look into this whole question is duly established. That may not be the whole solution, but it is the essential factor. Unless such a step is taken, any system of specialist committees is unlikely to work really effectively. The fourth report from the Select Committee on Procedure provides evidence which should be noted and used by all who recognize the value of informed public discussion in the formation of public policy—above all where scientific and technical factors are involved.

THE MAMMALS

Mammals of the World

By E. P. Walker, F. Warnick, K. I. Lange, H. E. Uible, S. E. Hamlet, M. A. Davis and P. F. Wright. Vol. 1, Pp. xlviii + 644. Vol. 2, Pp. viii + 1,500. Vol. 3, Classification Bibliography, Pp. xii + 769. (London: Oxford University Press; Baltimore: Johns Hopkins Press, 1964.) 300s per set.

THE mammalian fauna of the world at present consists of something between 4,000 and 4,500 living species divided into about a thousand genera—1,044 are recognized as valid in this work, which gives an illustration of all but four of them. The validity of genera as of species is however, often a matter of opinion that varies widely between the 'splitters' and the 'lumpers' among taxonomists; Walker himself speaks of the "twelve to fifteen thousand species" of mammals, a generous total even for a splitter.

Ernest P. Walker has been amassing the material for these books for more than thirty years, twenty-seven of them while he held the post of assistant director of the National Zoological Park at Washington, D.C. After his retirement the completion of the work was supported for seven years by funds from the National Institutes of Health, and the publication was sponsored by the New York Zoological Society. As the President of that Society says in the foreword, "The heroic task Mr. Walker set himself was to find and reproduce a photograph of a living representative of every genus. If he has not quite accomplished this, he has missed by the narrowest of margins and only because the genus is too obscure or the

otograph hidden where world-wide enquiries could not find it". He has had perforce to use some photographs of stuffed animals in museum collections, and occasionally reproduce drawings from original descriptions. The illustrations nevertheless form a unique and extremely valuable gallery, for they have been carefully chosen to convey a "better image of the animals than could be given by a word picture... many attractive and appealing photographs have been rejected because they did not show the characteristic form of the mammals to the best advantage". More than one picture is provided to illustrate some of the major genera, and there are many insets of important anatomical and osteological details.

The illustrations are accompanied by a concise text summarizing all that is known of the members of each genus; for many genera all recorded information is given in a few paragraphs, such is our lack of knowledge. Information, whenever available, is given about the number of species in each genus, the distribution, measurements and weights, coloration, type of body covering, structural peculiarities, habits, food, gestation period, number of young in a litter, economic importance, and the vernacular as well as scientific names. A page or two of introductory text is also given to each order and each family. A useful feature is the listing of museums holding specimens of mammals that are very rare in collections. A table showing the world distribution of the genera of recent mammals occupies twenty-four pages of introductory matter and, by means of a simple regional code and few footnotes, makes much useful information available at a glance. The text and illustrations together with a selected bibliography of about 4,500 titles occupy the first two volumes; the third volume, which is available separately for the more specialized worker contains a catholic bibliography of about 50,000 titles, containing many references of a popular character as well as those of serious scientific content. The pagination runs straight through volumes 1 and 2, and an index to the whole work appears at the end of both volumes; the end-papers carry scales for the comparison of metric and U.S. units of measurements.

The naturalist's first feeling on opening these volumes is one of surprise and delight at their completeness and comprehensiveness; his next, one of amazement that anyone should have contemplated undertaking such a staggering task, still more that he should have finished it successfully. Here are pictures and descriptions of rare and obscure mammals that hitherto had been no more than scientific names in fauna lists—often not even that—as well as pithy summaries of the biology of more familiar forms. It is of equal value to the general naturalist as a review of the mammalian fauna of the world, as it is as a reference book and guide to the literature for the specialist.

Although no one has approached the author's diligence in searching the literature, seeking information by correspondence throughout the world, in personal observation and study, and in developing a high degree of skill in photography, it would be too much to expect human endeavour to avoid occasional inaccuracies in a work of such great size. The state of Mr. Walker's health compelled him to pass some of the editorial burden to his colleagues during the last four years of the marathon, and he handsomely acknowledges their help for doing the "work that I should have done, but my declining energy prevented me from doing my part". There are, inevitably, some misprints, especially in unfamiliar geographical names, and such errors as "8 vol." for "8vo." in the bibliography. A few more serious errors have crept in, especially in the sections dealing with those orders of mammals with which the author presumably had less personal experience, so that he had to rely on others with consequent occasional misunderstanding. As examples one may mention the photograph of young seals on p. 1302, which, according to the caption, are common or harbour seals, *Phoca vitulina*, but are unmistakably the young of the harp seal

Pagophilus groenlandicus; or the photographs on p. 1129 labelled "Common or Harbor Porpoises (*Phocaena phocaena*)" which plainly represent the bottle-nosed dolphin, *Tursiops truncatus*—the error here may have arisen from the unfortunate difference between the American and English use of the names "porpoise" and "dolphin". Mr. Walker himself realizes that the devil is ever at hand to frustrate man's striving for perfection, and asks readers who find errors or who know of better photographs or additional facts to communicate with the publishers so that improvements can be made in a future edition.

It is, however, really ungenerous to point out the few blemishes in so splendid an achievement, and all naturalists, especially those who concentrate their studies on the mammals, are deeply grateful to Mr. Walker and his team for consolidating the foundations on which their work is based. The three volumes are not cheap but they are well worth their price, and considering that they contain nearly 1,800 half-tone illustrations it is surprising that they do not cost more; the typography, paper and binding are excellent.

This is one of the major contributions of the century to the study of mammalian biology. The author and his colleagues are to be congratulated on their unremitting labours, and the National Institutes of Health, the New York Zoological Society and the Johns Hopkins Press all gain the highest credit for the parts they played in bringing them to fruition.

L. HARRISON MATTHEWS

SALT TOLERANCE IN PLANTS

Physiological Basis of Salt Tolerance of Plants

(As Affected by Various Types of Salinity.) By B. P. Strogonov. Translated from the Russian by Prof. A. Poljakoff-Mayber and Dr. S. M. Mayer. Pp. 279. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1964.) 88s.

AT a time when more and more countries are embarking on ever-increasing schemes for the irrigation of vast areas of arid land, it requires no effort of imagination to appreciate the potential usefulness and relevance of a book dealing with the physiological basis of salt tolerance in plants.

Physiological Basis of Salt Tolerance of Plants was first published in the U.S.S.R. in 1962, and we are indebted for its rapid translation into particularly lucid and easily readable English to Prof. Poljakoff-Mayber and Dr. Mayer working under the auspices of the Israel Program for Scientific Translations. In a note at the beginning it is stated that the translation was undertaken because this was the first attempt to summarize in one book the information available in this field; it contained a great deal of factual information not readily available to Western scientists, and presented a number of ideas not previously adequately stressed in work on salt tolerance. There can be little doubt that these claims are fully justified by the subject-matter of the book.

In the first three chapters, Dr. Strogonov reviews the present state of the physiology of salt tolerance, the mode of action of salts on the plant, and theoretical considerations of experimental results, and this section provides a valuable and stimulating introduction to the literature, especially that from the U.S.S.R. on this subject. In the following eight chapters a series of subjects is dealt with one by one, each directly related to the growth of plants under saline conditions. These include the effect of salinity on development and anatomical structure; water relations and adaptation; nitrogen metabolism, and effects on the soil microflora, and a contribution on practical means for increasing salt tolerance of plants. In each of these chapters an extensive review-type introduction is followed by a section in which the results of experiments performed by Dr. Strogonov with cotton are presented by means of

tables and illustrations, and finally a concise summary of these results is provided. This method of presentation is not entirely successful since it provides the reader with a very large bulk of rather indigestible experimental results, and, owing to the absence of a discussion of the results by the author, considerable effort is required to correlate the experimental results reported with the information detailed in the introductory review of the literature.

Dr. Stroganov stresses that the book is concerned not so much with observations of conditions arising from salinity as with the mechanism of the action of excess salts on plant growth, and the specific effect of the type of salinization of the substrate. In particular, the importance of distinguishing between osmotic effects and toxic effects is emphasized. It is suggested that the toxic effects are due not directly to the effects of the salts themselves but to interference with the normal metabolic processes of the plant resulting in the accumulation of toxic substances such as ammonia, hydrogen peroxide or putrescine.

The value of the book is wantonly reduced by the complete absence of any sort of index, and also by the quite appalling quality of the illustrations. Nevertheless it does provide a useful and provoking review of the present knowledge on the subject, and, to the Western scientist, an excellent bibliography of a large body of inaccessible Russian work. It should provide a considerable stimulus to a branch of plant physiology which, in view of its outstanding practical importance, has been sadly neglected in recent years.

P. A. THOMPSON

RESEARCH IN PHOTOSYNTHESIS

Photosynthetic Mechanisms of Green Plants

(Papers presented at a Symposium sponsored by the Committee on Photobiology of the National Academy of Sciences-National Research Council, October 14-18, 1963.) (Publications No. 1145.) Pp. ix + 766. (Washington, D.C.: National Academy of Sciences-National Research Council, 1963.) n.p.

THIS volume contains the papers presented at a symposium sponsored by the Committee on Photobiology of the National Academy of Sciences-National Research Council, in October 1963.

It provides a wide, if uneven, coverage of the field of photosynthesis to that date, and is divided into ten main sections, including spectroscopic and fluorescence studies; biochemical studies of electron transport paths, and of isolated electron carriers; enhancement studies; respiration, photosynthesis and hydrogen metabolism; functions of pigments; chloroplast structure, mechanism of phosphorylation; carbon metabolism.

The volume contains seventy-five papers, of ten pages average length. Not unexpectedly, these differ widely in content, in presentation and in style. Some authors make a real attempt to review work in their particular laboratories, and to synthesize a picture of the mechanism of photosynthesis from the confusion of experimental data, but others present only isolated experimental data, thinly or thickly spread. Inevitably the volume lacks cohesion, and would have been better for a more uniform presentation. Very little of it is easy reading, but one feels that to include papers in which the text, the figures, and the figure legends are each in separate sections is asking too much of any reader. Quick publication is an important aim, but one feels that the volume would have been much more valuable had more rigid instructions for presentation been enforced.

The volume includes useful discussion of the nature of the long-wave absorbing pigments, and of the trapping centre of System I, which also serves to direct attention to our ignorance of System II. Work on biochemical mutants and their contribution to our present picture of photosynthesis is well covered. The volume emphasizes

how a wide range of techniques and experimental approaches combine to give a reasonably coherent, incomplete, view of the process, and much of the discussion centres around this picture of two photo-systems acting in co-operation with one another. The nature of the biochemical events set in motion by the absorption of quanta in each photo-system, and the mechanisms of the co-operation between them, provide much of the discussion and reflect the amount of effort at present devoted to these aspects of the subject.

By contrast, there is very little discussion of new information on the processes of energy transfer from the site of the initial absorption of a quantum to the active centre from which the subsequent biochemical changes arise. Nor is there evidence presented on the transformation of excitation energy in oxidation-reduction reactions at the trapping centre—another of the major unsolved problems in the field. Thus the book, both by its content and its omissions, presents a useful picture of the present state of the subject.

There is a seven-page editorial summary, which does something to draw together the wide range of experimental results and of hypotheses, but inevitably, at such a length, this can only highlight the more important points covered, and direct attention to areas of strong interest or extreme ignorance. One would like to read much more complete, critical assessment of the papers presented. Thus as a review this book is less satisfactory than other recent reviews of the field, and its value rather as a source book. Unfortunately for this purpose an index becomes a prime necessity and this is entirely lacking—doubtless a sacrifice to rapid publication. The book is essential reading for those working in the field of photosynthesis or in related fields, but it is a book for those already familiar with the literature; it is too heavy going to be in any way an introduction to the subject even for advanced students. With these limitations, it provides a valuable collection of papers covering a range of work which is otherwise widely scattered, and will be useful as such.

E. A. C. MACROBBIE

INDIAN TIMBERS

Indian Woods

Their Identification, Properties and Uses. Vol. 2: Linaceae to Moringaceae. Pp. x + 386 + plates 31-63. (Delhi: Manager of Publications, 1963.) Rs. 32-50 n.p.; 75s. 10d. 11.70 dollars.

THIS is the second of a series of volumes (the first of which was published in 1958) describing the timbers of India which are already commercially important or which are likely to become so as timber supplies run short. In the present volume the woods of 263 species are described, and these belong to 23 families ranging from Linaceae to Moringaceae. Descriptions and editing are mainly by S. S. Ghosh, K. R. Rao and S. K. Purkayastha, who have been supported by a team of assistants and specialist colleagues. Dr. K. A. Chowdhury, the senior joint author of the first volume, has revised the drafts of twenty of the present family descriptions and has also helped to select the photomicrographs.

The present volume is in the same style as the first. The reader is told under each family the number of genera and species of which it consists, and there are notes on economic plant products. Then follows a description, based mostly on naked eye or lens characters, of the gross structure of the timber of each of the species selected for inclusion in the book. Each description of the structure is followed by notes on durability, liability to attack by insect or fungus, working qualities, availability of supplies and, finally, uses. Reference numbers of the wood specimens on which the descriptions are based are given, and at the end of each family description there is a biblio-

aphy. With some of the larger families there are keys for the identification of the genera based on wood structure.

At the end of the book there are four appendixes dealing, respectively, with mechanical properties, classification of woods according to anatomical structure, classification of woods according to uses and, finally, recent name changes. In the second of these, the genera are very usefully listed under the diagnostic characters by which they can most easily be identified. It seems a pity that the name changes in Appendix IV are not covered under "Synonymy" in the main body of the text. There are 197 photomicrographs, mostly of excellent quality, showing the end-grain appearance of the different woods, and the book closes with separate indexes to (i) scientific names, and (ii) trade and common names.

This excellent book deserves a much better cover, for it will undoubtedly have to stand up to the hard wear that frequent consultation entails. C. R. METCALFE

TAXONOMIC AND EXPERIMENTAL BACTERIOLOGY

Manual for the Identification of Medical Bacteria

by S. T. Cowan and the late K. J. Steel. Pp. x+217. Cambridge: At the University Press, 1965. 50s.

Theory and Practice in Experimental Bacteriology

by G. G. Meynell and Elinor Meynell. Pp. xii+288+4 plates. (London: Cambridge University Press, 1965.) 60s. net; 9.50 dollars.

THE demand for diagnostic tables for the common medical bacteria by these authors was so great among clinical bacteriologists and others that it was inevitable that they should produce a book on the subject. It is therefore most regrettable that K. J. Steel, who contributed much to this work, did not live to see the proofs.

The *Manual* is clear and well produced, written with authority and an insight which at times is almost embarrassing; for who has not at one time or another been tempted to create a new species rather than carry out the necessary work to put an organism into its right place in an existing species. The book is centred on the two- and sometimes three-stage tables, which are easily read and clearly understandable to the bacteriologist. These do not, however, by themselves characterize organisms, but as the authors state, they focus attention on the most valuable of taxonomic tests. The early chapters are devoted to classification and nomenclature, the importance of obtaining pure cultures, and a useful chapter is included on the much-vexed problems associated with media preparation and sterilization. There follows a chapter on characterization in which the primary and secondary tests for the first and second stage diagnostic tables are discussed. The authors then get down to describing characters of Gram-positive and Gram-negative bacteria, and include what they term "minidefinitions" which give the main characters of each organism succinctly and precisely. These should be very helpful to harassed clinical bacteriologists who wish to refresh their memories as briefly as possible. Following these chapters is one on refractory organisms of uncertain characterization; and a short chapter on taxonomic implications (for those interested) ends the discursive part of the book.

There are seven appendixes, consisting of laboratory notes covering instructions for media preparation and control, staining reagents, characterization tests including rapid methods some of which, it is claimed, are sensitive and give more clear-cut results than the standard characterization tests. Finally, there is a list of recommended strains of test organisms with conditions for their maintenance; and the book ends with a comprehensive list of references.

The *Manual* will undoubtedly be popularly received in most diagnostic laboratories, and this must be due in no

small measure to the realization by the authors of the different points of view between the taxonomist and the clinical bacteriologist, or the taxonomist and the epidemiologist. The majority of workers who will use this book will undoubtedly have ideas as to the probable causal organisms to be isolated from a known specimen. Whether their assessment is correct or not, they can with value use the progressive approach to identification indicated by the tables, and probably arrive at a correct diagnosis. Isolation of pure cultures of organisms from clinical specimens is the prime requirement, and it seems a pity that more comprehensive advice on this problem, and on the use of enrichment media, was not included within the stout covers of this admirable handbook.

Experimental microbiologists and research students will find themselves well served by the efforts of Meynell and Meynell in a book which is packed with information about measurement, both quantal and quantitative, of micro-organisms, and which does not contain one single dull or uninteresting page. This is a fascinating guide to theoretical principles underlining the significance and importance of bacteriological experimentation, and can be approached with minimal understanding of simple statistical terms.

The book commences with a chapter on measurement of bacterial mass and number, neatly describing the various methods in use and showing clearly that in estimation of the precision of viable counts the presence of sampling errors lessens the effect of technical error. The section on quantitative measurement of bacterial growth could be read with profit by undergraduate students of bacteriology.

The next four chapters deal with culture media; oxidation-reduction potential and anaerobiosis; the kinetics of sterilization, including sections on chemical disinfection and filtration; and microscopy. The penultimate chapter, dealing with quantal responses, Poisson distribution and normal and log-normal distributions, is supremely clearly written, and with well-chosen examples makes relative simplicity out of what, to a large number of biologists, are complex and difficult subjects. The book ends with a chapter on miscellaneous techniques.

Not the least contribution of this book is the inclusion of a variety of most useful tables which would be of considerable value in any microbiology laboratory.

D. ALLAN

SKIN AND ITS DISEASES

The Epidermis

Edited by William Montagna and Walter C. Lobitz, jun. Pp. xx+649. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 107s. 6d.

FOR a variety of reasons which are familiar to most scientific workers, the published proceedings of symposia rarely contain any information which is not available elsewhere. They are, however, sometimes of value in two ways. First, they may bring specialized information to the notice of a reader from an allied field of research with which he is not familiar because of its publication in journals not immediately available to him. Secondly, symposia may be used by investigators to take a broader look at current thought in their own field. Both these aspects make their appeal on reading the papers presented at a symposium on "The Epidermis" which was sponsored by the Division of Dermatology of the University of California. It was made possible by a grant from the U.S. Public Health Service, the advisory committees of which felt the need for a series of such meetings on the biology of the skin.

The volume is dedicated to the late Prof. Stephen Rothman, a pioneer dermatological investigator, whose first chapter on "Keratization in Historical Perspective"

sets the high standards to follow. The book is large but contains a wealth of basic dermatological thought and fundamental information. The chapters range widely over embryology, keratinization, ultrastructure and histochemistry, carbohydrate, nucleic acid, sterol and lipid metabolism, permeability and blister formation. Many of them are contributed by the acknowledged experts in each field whether from the United States, Europe or Australia.

Philippe Sengel (Paris) describes his elegant experiments which have thrown so much light on the differentiation of cutaneous appendages in the embryo, and Dame Honor Fell summarizes the present studies on keratinization in organ culture of skin being carried out at Strangeways Research Laboratory. Mercer (Canberra), Brody (Stockholm) and Swanbeck (Stockholm) each give excellent accounts of their own work on the ultrastructure of the components of the horny layer in normal skin, and the deviations which characterize psoriasis. Kligman's (Philadelphia) chapter on the biology of the stratum corneum is especially readable, not only because of his own distinctive style of writing but also because he has directed attention to some of the more neglected biological phenomena in the epidermis. Epidermal cells in the stratum corneum become very much more cohesive to one another than in the basal, Malpighian or granular layers, and yet this cohesion is lost at the surface in such a way that the fully keratinized cells are shed in small flakes which are not normally perceived. An understanding of the mechanism by which such a change occurs should lead to valuable knowledge of many scaly dermatoses.

The organizing committee of this symposium were fortunate to succeed in 'capturing' so many outstanding scientists actively working on the biology of the skin. Drs. Montagna and Lobitz and the Academic Press have produced a volume which is a credit to the participants. There is an author index of the references used in all the papers, and a subject index. Typographical errors are very rare indeed. "Bellberg" for "Bettley" is repeated several times. For a book of this quality it is not overpriced.

C. D. CALNAN

ATOMIC AND MOLECULAR SPECTROSCOPY

Spectroscopy and Molecular Structure

By Gerald W. King. Pp. xiv + 482. (London: Holt, Rinehart and Winston, 1964.) 86s.

EXCELLENT advanced monographs on many different aspects of atomic and molecular spectroscopy are available, and articles in, for example, *Annual Reviews of Physical Chemistry and Advances in Spectroscopy*, enable research workers to keep abreast of present development. There is, however, at a different level, a need for an introductory text-book suitable for senior undergraduate or postgraduate teaching in chemistry or in physics. Dr. King's book fills some of the gaps admirably.

A very short introduction on spectroscopic technique is followed by chapters on wave-mechanics and the hydrogen atom, many electron atoms, diatomic molecules, the symmetries, rotations and vibrations of polyatomic molecules, and concludes with a discussion of the electronic spectra of polyatomic molecules and appendixes on operators, selection rules, character tables and physical constants. Each chapter has a short bibliography, and a collection of illustrative problems, some of which are very searching. Mathematical techniques are introduced progressively throughout the book, so that the later chapters are, reasonably, much more difficult than the early ones. However, the elements of group theory and of matrix algebra, required for the treatment of polyatomic molecules, are introduced both clearly and attractively.

There has necessarily been a rather careful selection of material, so as to limit the book to a convenient length.

Microwave spectroscopy is one of the subjects to suffer. Some description of the techniques would have been welcomed by many students, and the measurement of dipole moments and of nuclear quadrupole coupling constants has provided information of such wide interest that it is surprising that these subjects have been omitted. Again, chemists interested in the properties of complex compounds will find the discussion of the energy states of transition metal atoms and ions inadequate. The treatment of dissociation energies is also very brief (it would have been helpful to have included the paper by R. Mulliken (*J. Chem. Phys.*, **33**, 247; 1960) in the bibliography at the end of Chap. 6). But, it must be stressed that some selection must be made, and by and large this is a book on the energy-levels of atoms and molecules, and as very successful it is too.

The book is well produced and easy to read. The least successful features of the production are the six half-ton reproductions of spectra. There are very few misprints or mistakes. For example, the statement (p. 75): "Spin-orbit interactions increase rapidly with atomic weight, and are especially large in excited states of heavier atoms" is misleading. These interactions certainly increase rapidly with atomic number, but for a given configuration, say np , of a particular atom or ion, the spin-orbit coupling *decreases* rapidly with principal quantum number. Again, p. 211: "The Λ -type splitting seldom exceeds a few hundredths of a wave-number" should be replaced by "The Λ -type splitting *constants* seldom exceed a few hundredths of a wave-number". In the review copy, Fig. 6, 7 (p. 206) was inverted, and there is an obvious error in the printing of problem 8.2 (p. 314).

Nearly half the book is devoted to the energy-levels and spectroscopy of polyatomic molecules, and it is this which is its real strength. This is not an easy subject, but the author has succeeded in developing an account which is both lucid and stimulating. This will be recommended reading for many mathematically minded chemists and physicists, undergraduates and postgraduate alike.

R. F. BARROW

BASIC STATISTICAL TECHNIQUES

Statistics and Experimental Design in Engineering and the Physical Sciences

Vol. 1. Pp. xiv + 523. 84s. Vol. 2. Pp. ix + 399. 87s. By Prof. Norman L. Johnson and Prof. Fred C. Leone (New York and London: John Wiley and Sons, Inc. 1964.)

THIS book is intended to give students and research workers in science and, particularly, engineering a sound understanding of and facility with basic statistical techniques.

"The material in this book should cover two or possibly three semesters of applied statistics at the upper-division undergraduate level."

These two sentences from the preface indicate the authors' intention. Despite the number of books which aim at fulfilling this function, there is still a need for a good one. The book is long, nearly a thousand pages, and is divided into two volumes. The first volume has three chapters on probability theory describing the properties of the usual distributions, and also some of the distributions which are of practical interest but are often ignored, and chapters on estimation, testing hypotheses, tests of significance, regression and correlation which are not particularly well done and appear in almost any other book of this nature. There are chapters on order statistics and non-parametric methods, both of them clearly written, a long and detailed chapter on control charts, and a balanced chapter on the utilization of prior information. The second volume has a long section, more than two hundred pages, on the analysis of variance and the design

experiments and a chapter each on sequential analysis, multivariate analysis and sampling. There is an appendix of tables which is comprehensive enough to be useful, and a bibliography of statistical journals and tables. The examples, of which there are a good number well placed in the text, are mostly credible and instructive.

The general character of the book is in line with what the authors take as their definition of statistics, the scientific study of the analysis of quantitative data. It seems to me that by concentrating almost exclusively on the description and analysis of data, the book suffers from lack of balance. Thus the aim of the chapters on probability theory is to present the distributions which are usually used to describe engineering data, and this is done well enough. But there is no account of why one could expect to use a particular distribution in one class of problems but not in another, nor is there any indication that probability theory might be useful in investigating the structure of a problem. The normal distribution is introduced as being of importance because it fits much of observed data, and is then fitted to some data. Nothing is said about why this should be so. The Poisson distribution is discussed as a useful limiting case of the binomial distribution, but as most of the examples can be described more naturally in terms of the Poisson process, it is a pity the Poisson process is not mentioned. It seems odd that the book should contain an elegant treatment of the non-central χ^2 , t and F distributions but have no mention of stochastic processes. Again, the section on the analysis of variance is primarily concerned with the analysis rather than the design of experiments, and little is said of the merits or otherwise of the many designs for which the analysis is presented. The section on multiple linear regression gives several methods for inverting the design matrix, but says nothing on choosing it.

It is difficult to see this book being used as a text-book or engineering students. Most universities in Britain only have short courses in statistics for engineers, and as an introduction to the subject this book is not to be recommended. There is nothing new in the more elementary chapters, which consist mainly of explaining techniques rather than the underlying principles or general usefulness, and a knowledge of statistics based on these chapters alone would probably do more harm than good. To statisticians who do a certain amount of engineering consulting, however, the book might prove valuable, as there are a fair number of topics discussed which many books ignore.

N. E. DAY

PACIFIC GEOLOGY

Marine Geology of the Pacific

By Prof. H. W. Menard. (International Series in the Earth Sciences.) Pp. x+271. (New York: McGraw-Hill Book Company, Inc.; Maidenhead: McGraw-Hill Publishing Company, Ltd., 1964.) 12.50 dollars; 100s.

THE Pacific Ocean comprises nearly half the total area of the surface of the Earth: it is therefore an ambitious project to describe and discuss the geology of the underlying crust in one book. That it is possible at all results from the way in which the subject of marine geology has grown owing to the necessity of conducting operations several miles above the sea-floor. The facility with which rocks can be examined at close range on land led to the growth of geology through hand specimens up to the broader concepts of tectonics and global structures. Submarine geology, on the other hand, has largely developed from the broader studies of bathymetry and geophysical surveys, such as magnetism and seismics, that are necessitated by the inaccessibility of the bottom. Hand-samples are rare, and rigorously controlled sampling is still impossible except in a few special areas.

Prof. Menard has brought together, in a very readable form, nearly all that is known about the Pacific geology

and discusses it in terms of the broader concepts of the history of the ocean basins, and continental margins. Inevitably many of the data are mentioned only by reference but this has left the author freer to discuss the relative merits of the different theories presented. As one of the leading authorities on Pacific geology, many of the data have been obtained by Prof. Menard himself and many of the hypotheses discussed have been published by him over the past two decades. However, the book contains new material, especially in the form of summary diagrams, a bathymetric map of the whole Pacific (regrettably split into 14 sections to fit page size) and an admirable physiographic diagram of the north-east Pacific in a folder at the end. This diagram follows the style of those produced by Heezen and Tharp of the Atlantic and Indian Oceans but with the addition of 500-m contours in the basins.

But more important is the development of the new idea of the Darwin rise as an old and foundered mid-ocean rise, the importance of which in the Pacific has been overshadowed by the younger East Pacific Rise. The great east-west linear faults which are such a feature of the Pacific, are described in detail in Chapter 3, but a discussion of their relevance to crustal deformation is deferred to the later chapter on oceanic rises.

This book is much more than a treatise on Pacific geology. It contains a stimulating review of the features and processes of marine geology in general. Whole chapters are devoted to volcanism, manganese nodules and turbidity currents, while elsewhere new evaluations are presented of the composition of the seismic second layer, abyssal hills, changes of sea-level and the development of continental margins.

An attractive feature of the book, so often absent in the discussion of geological phenomena, is the order-of-magnitude calculations made about such processes as transportation of sediment through submarine canyons and the origin of sea-water. In the many problems where our knowledge is least sure, Prof. Menard has frankly admitted it and given rein to imaginative speculation that is a challenge to future research.

This book is highly recommended as an up-to-date and well-presented account of marine geology both for the student and for all involved in research in this field.

A. S. LAUGHTON

A CENTURY OF ANTHROPOLOGY

A Hundred Years of Anthropology

By T. K. Penniman. With contributions by Beatrice Blackwood and Dr. J. S. Weiner. Third edition, revised. (Duckworth's 100 Years Series.) Pp. 397. (London: Gerald Duckworth and Co., Ltd., 1965.) 42s. net.

THE third edition of Penniman's survey brings up to date the story he first unfolded in 1935. Two extra chapters, by Dr. J. S. Weiner and Miss Beatrice Blackwood, review developments in physical anthropology and in Americanist studies, respectively, over the past thirty years. Readers who can look back to the first appearance of Penniman's classic will remember the admiration it evoked in anthropological circles at that time. The common opinion was that the several branches of anthropology had become too specialized for any one scholar to have competence in all. Pupil and later colleague of R. R. Marett, Dudley Buxton and Henry Balfour, whom he succeeded as curator of the Pitt-Rivers Museum, Penniman showed that it was still possible for an all-round ethnologist to keep abreast of the main trends in all branches of the subject. The extra chapters in the present edition eloquently testify to the end of that epoch.

A history as comprehensive as this could easily degenerate into a catalogue of names, dates and titles of publications—Penniman avoids this by his narrative method. Defining 'anthropology' as the generic science

of man embracing the biological, historical (and therefore archaeological), cultural and social conditions of his existence, he directs attention to the major figures, those whose discoveries and theories set the general patterns of anthropological enquiry for a period of development. Lesser figures are dealt with more summarily in relation to the topics to which they made contributions rather than the issues of principle that were uppermost in their time.

To find Darwin's, Herbert Spencer's and E. B. Tylor's work and influence discussed at length—and, be it added, with a sure sense of what was significant in this for their successors—seems natural enough. But how many of us are aware of the seminal influence exercised by Bastian (1826–1905) during his life-time? Indefatigable traveller and encyclopaedically learned, he is ranked by Penniman with Darwin and Tylor. Bastian is famous for the hypothesis of the "psychic unity of mankind", which he attributed to the universality of a limited number of "elementary ideas". Penniman's account of how he reached his theories, what he really meant by them and how they served to unite the incipiently divergent evolutionary and diffusionist trends of the period is typical of the exposition followed throughout.

Penniman divides the history of anthropology into five main periods: (1) The "Formulary Period", from the Greeks to 1835; (2) The "Convergent Period" (1835–59); (3) The "Constructive Period" (1859–1900); (4) The "Critical Period" (1900–35); (5) The "Period of Convergence and Consolidation", since 1935. For each of the modern periods, each branch of anthropology is treated under a separate rubric, but the details of authors and publications are bound together by keeping common and general tendencies to the fore.

Up to 1935 the story is told with a masterly command of the literature and admirably balanced judgment. To take an instance at random, one would have to search diligently in the anthropological literature of the 'thirties to find comments as judicious and sympathetic as Penniman's on the significance of psycho-analysis for anthropology. The part which traces more recent developments is, inevitably, more sketchy. The excellent index and the careful bibliographical documentation deserve particular commendation.

M. FORTES

THE NON-GUILTY PARTY

Prisoners and their Families

By Pauline Morris. Pp. 327. (London: George Allen and Unwin, Ltd., 1965.) 50s.

MOST of us, fortunately, are relatively law-abiding citizens and we are unlikely in the course of our daily work, and may be even during the whole of our lives, to come up against the problems which result from the imprisonment of law-breakers. Occasionally a sensational crime, such as "the great train robbery", and, even more sensationally, the escape from prison of one or more of the convicted train robbers, will attract our attention and give rise to discussion about the penal system and imprisonment as a form of punishment, but it is very doubtful whether most of us will spare a thought even then for the prisoner and his family. On the whole, we prefer to leave the problems of crime and its punishment to the police, the courts and the Home Office (Prison Department) and the few worthy citizens who are prepared to give voluntary service as prison visitors. But are we entitled to ignore so easily the social effects of imprisonment as a method of social punishment, and can we be quite sure that when an offender is punished we do not impose additional punishment on his family?

A remarkably thorough study of the problems encountered by the families of prisoners in Britain has recently been made by Mrs. Pauline Morris, and the conclusions

derived as a result of her investigations should make all think more seriously about the social effects of imprisonment. The great virtue of this book is that it records the results of a truly scientific investigation as yet it is written with warmth, insight and compassion. Despite the appalling misery which Mrs. Morris all too often has to describe, she never allows her emotions to deflect her from the path of strict objectivity and scientific analysis of the data so carefully and systematically collected.

The primary object of the research project was "to elicit facts upon which penologists and administrators might base future policies" and, curious as it may seem, this "is the first attempt in this country to look at the problems of the families of prisoners on a national scale. As a result of previous research undertaken by Mr. Morris "amongst the recidivist populations of two maximum security prisons" which showed "that a high proportion of men appeared to have severe family problems", a number of hypotheses were put forward and explored in this new investigation. For example, the "family relationships following upon conviction and imprisonment will follow a pattern set by family relationships which existed before imprisonment", and "the adjustment of the family to imprisonment will vary with the type of offence, and with the extent of previous criminal experience".

A national sample of male married prisoners (837 in all) was selected for interview and permission was sought from each prisoner for his wife (legal or otherwise) to be interviewed at home. In addition, an intensive study of the families of 100 prisoners living in the London area was undertaken. The organizational problems involved in arranging the interviews and carrying them out were enormous, but the care taken and the controls exercised in planning the project and in its execution are of the highest scientific standards. Indeed, for those who still doubt whether scientific methods can be applied to investigations of human and social phenomena, Chapter 1 of this book on "The Design of the Enquiry" should be compulsory reading.

The picture which emerges of the varieties of problems encountered by the families of prisoners makes interesting and sometimes heartbreaking reading. Mrs. Morris is to be congratulated on producing such a vivid and living account of the real life problems faced (not always squarely) by real live persons less fortunate (and on occasion less lucky) than most of us. Inevitably there were methodological difficulties which could not always be solved, as, for example, when the 'story' given by the prisoner about his family circumstances differed substantially from that given by his wife. On further investigation "it transpired that the wife shared herself between two 'husbands', both of whom happened to be in gaol at the time of our interview with her. Since this fact was unknown to the interviewer, it was not possible to tell that the information the wife gave related to a different 'husband' from the one whom we actually saw!" Fortunately, there were very few discrepancies of this kind in fact, because of the exacting standards applied by Mrs. Morris to this investigation.

This book undoubtedly makes a significant contribution to our knowledge of a social problem about which all too little was known in the past. It should also provide a firm basis for developing an enlightened penal policy in the future. Mrs. Morris and her colleagues have obviously not given us all the answers we need to solve the difficult problems of punishment, but they have produced an intensely interesting and valuable investigation which can be thoroughly recommended to those (and I hope they would be many) who have an interest in the problems of their less fortunate fellows and in the machinery used by society to inflict punishment on offenders, and, inadvertently, their families.

D. C. MARSH

Probability and Statistics

H. Freudenthal. Pp. v+139. (Amsterdam, London and New York: Elsevier Publishing Co., 1965.) 30s.

A SCIENTIST or technologist with modest mathematical skill and no fear of unfamiliar notation could gain considerable insight into statistical thought from this book. He would not advance far in learning standard statistical techniques for use in his own problems because the book does not attempt their systematic presentation. Prof. Freudenthal's strength lies in a largely intuitive approach allied to an attractively easy style. He does not retreat from difficulties, but he refuses to conceal the essential features of a proof by trappings of mathematical rigor appropriate only to more advanced texts.

Early chapters are largely concerned with probability theory, made vivid by excellent simple examples of independence and conditionality. The implication that sampling with replacement is theoretically preferable to sampling without replacement is strange, but possibly translation from the Dutch has permitted entry of a confusion between simplicity of theory and practical desirability. Prof. Freudenthal uses the central limit theorem to justify widespread practical dependence on the normal distribution. The final one-third of the book—as chapters concerned with sampling inspection (including sequential sampling), distribution-free tests, games and strategy, and population genetics. None of these topics is taken far, and all are regarded a little abstractly as playgrounds for mathematicians rather than as fields of investigation in which the statistician must make a great contribution. In the context of a book that may make an intellectual appeal to mature readers but that is not suitable as an introductory text, they play their part well. The book can be confidently recommended to those who find its form seeming to meet their needs, but disregarded as of no fundamental importance by those to whom its somewhat unusual style makes no appeal. Of few books on probability and statistics can both these statements be made!

D. J. FINNEY

ALGOL 60 Implementation

The Translation and Use of ALGOL 60 Programs on a Computer. By B. Randell and L. J. Russell. (A.P.I.C. Studies in Data Processing, No. 5.) Pp. xiv+418. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1964.) 84s.

THE introduction of automatic computer languages has opened up the use of computers to a large public by making the programming of digital computers much easier. This is due to the development of compilers: the large programmes which translate automatic languages, which are relatively easy to use, into machine languages which are much more difficult to use. Initially automatic languages and their compilers were very much empirical *ad hoc* affairs; the writing of compilers was more of a craft than a science. But recently this state of affairs has changed, an important step in this direction being the publication some five years ago of the ALGOL report. Using the notations and techniques of mathematical logic, this defines precisely a programming language suitable for scientific computations. This stimulated the systematic study of compiling methods and many papers on the subject began to appear.

This book is an excellent and welcome contribution to the literature; it will make more accessible to a large public some of the more commonly used and basic compiler techniques. The compiler described produces in one pass an object programme which is obeyed interpretively by a control routine during run time. This may not be very efficient, but many of the concepts explained in this book are relevant to other forms of compilers. In particular, repeated use is made of the concept of stack or push-down store.

Because this is among the first books on the subject, the form and contents of the book may put off the uninitiated reader, but it is well worth persevering with. An attractive aspect of the book is the large number of very short programmes illustrating the many difficulties a compiler has to deal with.

I. M. KHAZAZA

Einführung in die Atomphysik

Von Dr. Wolfgang Finkelburg. Neunte und Zehnte Ergänzte und Neubearbeitete Auflage. Pp. xii+552. (Berlin, Göttingen und Heidelberg: Springer-Verlag, 1964.) 45 D.M.

THE present issue of *Einführung in die Atomphysik*, by Prof. W. Finkelburg, is the nineteenth and twentieth reprint, revised and brought up to date by the author, who is a member of the Siemens-Schuckertwerke group in Erlangen. It is intended for physicists in the applied fields, engineers, chemists and technical personnel. Its scope is very wide, comprising, besides atomic physics, extensive chapters on quantum mechanics, nuclear physics, 'elementary' particles, molecular and solid-state physics. The author is manifestly an experienced pedagogue who leads the reader in carefully planned steps through the various phases of an argument. It is a magnificent and, on the whole, successful effort to provide a readable text of a complex scientific field.

It is, however, clear that the maximum one can achieve in the circumstances is plausibility, which is probably what the author aimed at. The question then arises if it is a good plan to incorporate a fair proportion of the wave mechanical formalism (according to Sommerfeld), without the mathematical background (see p. 360, where the formula is completely without meaning). It must be admitted that the figures of electron distribution and some wave functions are excellent.

The book, as such, comes up to the expectation one holds for a production from the publishing firm of Springer; it is quite cheap at 45 D.M., and will no doubt greatly contribute to the education of that most important part of the scientific community who apply science.

E. BRETSCHER

Physique des Semiconducteurs

Comptes Rendus du 7^e Congrès International. (Physics of Semiconductors: Proceedings of the 7th International Conference.) Pp. xxii+1368. (Paris: Dunod, 1964.) 145 francs.

PHYSIQUE des Semiconducteurs: Comptes Rendus du 7^e Congrès International contains about 200 distinct original items, five of which are reports on symposia on related topics. It will be an invaluable work of reference pointing to other and fuller papers on certain topics, and indicating the major aspects of present interest in the field. It has been remarked that this field, like women, has become more sophisticated with age, and this volume certainly gives evidence in favour of this assertion. More accurate measurements, and more detailed calculations are reported here, of quantities the broad significance of which has in many cases been known for some years. This impression is strengthened by the fact that the details of the symposia on radiative recombination, radiation damage, and solid-state plasma effects, all very active fields, have been published separately. This still leaves interesting effects within the scope of this volume—effects which were not expected two years before (during the corresponding meeting at Exeter in 1962). The relativistic correction to band structure calculations is an example. The importance of lasers is another example, for they have enhanced the interest in studies of electron transitions in solids, which may compete with radiative transitions. Papers in this volume deal with these and other important effects. It is clear that this field is con-

tinuing to throw up important new developments, and it is reasonable to expect an average of one important development per annum to be maintained until the next volume of this series (reporting the meeting in Tokyo in 1966) is reviewed in these columns.

P. T. LANDSBERG

Counterexamples in Analysis

By Prof. Bernard R. Gelbaum and Prof. John M. H. Olmsted. (The Mathesis Series.) Pp. xxiv+194. (San Francisco, London and Amsterdam: Holden-Day, Inc., 1964.) 7.95 dollars.

THE schoolboy learns that the harmonic series does not converge, although its n th term tends to zero; the undergraduate is shown Weierstrass's function, which is continuous but not differentiable; at a later stage, a mathematician's pleasing speculation may be disrupted by an instance of its falsity. The construction of counterexamples is a not unimportant part of the technique of the analyst, as, for example, in the theory of Fourier series, and this collection of some 250 items may serve for profit as well as for amusement. The authors have made a selection from number systems, functions, limits, differentiability, integration, convergence, set and measure theory in one and two dimensions, metric, topological and function spaces. Almost any dip will come up with something pleasing; a random opening provided functions f and g such that f^2 and g^2 are integrable but $(f+g)^2$ is not. But the book will be more seriously useful to the teacher of analysis, who is often in need of examples of this type to show why the conditions imposed on a theorem are necessary, and to the young research worker who may have to test heuristic ideas by hard fact.

T. A. A. BROADBENT

Radioactive Fallout, Soils, Plants, Foods, Man

Edited by E. B. Fowler. Pp. 317. (Amsterdam, London and New York: Elsevier Publishing Company, 1965.) 80s.

THE evaluation of the significance of dietary contamination with radioactive fall-out requires the co-operation of many disciplines, and our understanding of this subject has owed much to meetings at which meteorologists, health physicists, agricultural scientists and medical radiobiologists have brought together the relevant information from their various subjects.

Two particularly important meetings of this type were arranged in 1959 by the University of Minnesota and the Food and Agriculture Organization in Rome. The publications to which they led in the following year largely paved the way to the first authoritative and comprehensive assessment of mechanisms of dietary contamination which the United Nations Scientific Committee on the Effects of Atomic Radiation included in its 1962 report. Other meetings with the same general objective had meanwhile been held, among them being a symposium of the American Chemical Society, at Cleveland, Ohio, in April 1960.

The volume under review is based on the papers presented at the Ohio meeting. The editor's preface shows his consciousness of the disadvantage of delay in publishing reports of symposia on rapidly developing subjects, and an endeavour was made to revise and to 'up-date' contributions. This was notably achieved in the discussion of the "Transfer of Fallout Radionuclides from Diet to Man", by Drs. Wasserman Lengemann, Thompson and Comar, in a chapter which contains about half the references to publications dated 1962 or later which are to be found in the entire volume. Read in 1965, some of the other chapters are mainly of historical interest. Not only are a number of transfer routes of much smaller importance than was sometimes thought in 1960 but also interest in the significance of fall-out now centres primarily on the effects of weapon tests in 1961

and 1962 which were of considerably greater magnitude than the earlier series.

Piante Medicinali

Chimica Farmacologia e Terapia, Vol. 2. Da R. Benign C. Capra and P. E. Cattorini. Pp. 731-1832. (Milan: Inverni e della Beffa, 1964.) L.12,000.

THIS is the second part of a comprehensive Italian work on medicinal plants, Volume 1 having already been reviewed in these pages (*Nature*, 196, 609; 1962). Plants are arranged according to their Italian common name. Volume 1 covered the letters A-H. The present volume deals with the rest of the alphabet, representing some 120 different species. As in the case of the earlier volume, there are notes on etymology, nomenclature, habitat, parts used, active principle, therapeutical properties, pharmacology, and chemical composition. There is special emphasis on the chemistry of the plants, which is covered in some detail and the latest information incorporated. This applies particularly to plants that have recently attracted special attention, for example, *Rauwolfia serpentina* has 149 pages devoted to it and there are more than 800 references. *Strophanthus* (*Strophanthus kombé*) covers 25 pages, with 161 references.

Other well-known medicinal plants dealt with in this volume include golden seal, Iceland moss, ipecacuanha, jaborandi, liquorice, lobelia, clive, opium poppy, pepper mint, rhubarb, senna and strychnine or nux-vomica. Many of the other species treated, although well known are of little importance medicinally to-day. Nevertheless it is of value to have so much information in relation to them brought together. The common horse-chestnut (*Aesculus hippocastanum*) is not usually looked on as a medicinal plant, yet 14 pages are devoted to it along with 38 references. This may be because of the saponin it contains.

Pollen Physiology and Fertilization

Edited by H. F. Linskens. (A Symposium held at the University of Nijmegen, The Netherlands, August 1963.) Pp. xii+257. (Amsterdam: North-Holland Publishing Company, 1964.) 80s.

IN August 1963 a symposium was organized at the University of Nijmegen to bring together a number of people interested in the study of pollen tube formation and germination, and the processes leading up to the formation of the zygote in higher plants. The papers and discussions given at this symposium are now published under the title *Pollen Physiology and Fertilization*, edited by Prof. H. F. Linskens.

The symposium was organized in seven sections each of about three or four papers followed by a tape-recorded discussion. Subjects included the physiology of the embryo sac, and the biochemistry of pollen wall formation; pollen tube metabolism; the effects of boron on growth; chemotropism and sections on controlled fertilization and incompatibility. Particular interest is derived from the high proportion of papers in which relatively modern techniques such as electron microscopy, histochemistry and *in vivo* methods of controlling fertilization are used to investigate the problems raised.

The publication of papers read at any specialized symposium inevitably results in the reappearance of a fairly high proportion of material already familiar as a result of its appearance in regular journals, and this is no exception. Nevertheless, this volume does provide a readily accessible collection in one place of contributions by a number of well-known authorities on the subject; and the convenience for comparison and survey which this provides, combined with the general high standard, or controversial interest, of the papers will make it a welcome addition to the collection of anyone interested in the physiology of pollen germination and fertilization.

P. A. THOMPSON

ORIGIN AND SIGNIFICANCE OF THE POWER OF VOCAL IMITATION: WITH SPECIAL REFERENCE TO THE ANTIPHONAL SINGING OF BIRDS

By DR. W. H. THORPE, F.R.S.

Sub-Department of Animal Behaviour, Department of Zoology, University of Cambridge

AND

MYLES E. W. NORTH

Milton Close, Muthaiga, P.O. Box 8225, Nairobi, Kenya

HERE are few abilities which separate man more clearly from other members of the animal kingdom than his powers of imitation. Even among the primates the ability to learn a new action as a result of having seen performed by another member of the species has only been established relatively recently; and convincing examples among mammals below the primate level are scarce indeed¹.

When we come to consider vocal imitation the difference between man and the other mammals is even more striking. Even with the chimpanzee a capacity for vocal imitation seems to be almost non-existent and no satisfactory scientific evidence seems yet to have been presented in behalf of claims made for the powers of vocal imitation among porpoises^{2,3}. This remarkable difference is considered by Konorski⁴, as a result of his analysis of various forms of speech disorder, as comparable with the audio-verbal aphasia which results from certain types of brain lesion in man. Lesions which have this effect are shown to have damaged either the postero-superior part of the temporal lobe, or to have severed the 'arcuate bundle' which originates in this area and runs to the lateral frontal regions. According to Konorski, it is a striking fact that there is nothing exactly comparable with this 'arcuate bundle' known in non-human mammals, and it is this absence which is thought to account for the lack of powers of vocal imitation.

When we come to compare the imitative abilities of the birds with those of the mammals, we find that while the ability of the former group to imitate bodily actions is probably even less than it is in mammals, the powers of vocal imitations are of an astonishingly high order, being even comparable in some cases with those possessed by man. The origin and significance of this difference raise, therefore, most puzzling problems. Unfortunately, on the neurological side, nothing can be said; for the investigation of the bird's central nervous system has not yet nearly reached the stage at which we can say whether or not there is any structure functionally comparable to the 'arcuate bundle' of the human brain. The only birds on which modern neurological investigations are being actively carried out are the doves; but it appears⁵ that these are incapable of imitation. We have, therefore, to come down to behavioural evidence, as this does indeed provide some interesting clues.

In the Oscines, or song birds, at least those of the temperate regions of the world, the most usual function of the full-song is to serve as a territorial proclamation by the male establishing claim to a territory and, as a substitute for fighting, defending it. Thus it serves as a signal which is sufficiently stereotyped to function as a recognition mark characteristic of the species. But it is well known (refs. in Thorpe⁶) that in many species the song is capable of sufficient individual variation within the overall specific fixity of pattern to differentiate one individual bird from another. Thus, the song comes to serve two functions—specific recognition and individual recognition.

This individual differentiation of the song is often developed by imitative learning, the bird in its first year either imitating its parents' song or, perhaps more often,

learning individual differences from other members of its species when it first comes to sing in competition with them during the process of establishing a territory during its first breeding season. Thus, chaffinches (*Fringilla coelebs*) reared in isolation produce an abnormally simple song which is mainly accounted for by the hereditary make-up. Only when the bird is reared in contact with its own kind does it develop the full species pattern and add the aforementioned individual characteristics. Thus, experience influences the selectivity for the song which will be imitated, and in early spring the bird tailors its own song to match the patterns which it has heard. There is, therefore, a functional explanation for the ability to imitate the vocalizations of one's own species even where the prime function of the song is territorial advertisement and defence.

But, as everyone knows, the imitative performance of a number of birds goes far beyond this. There are species, such as the starling (*Sternus vulgaris*), the mocking bird (*Mimus polyglottos*) and the marsh warbler (*Acrocephalus palustris*), which include notes and phrases from many other species in their own song. Even more remarkable are the 'true' talking birds, especially the members of the parrot family and the grackle, known as the 'Indian mynah' (*Gracula religiosa*), which can imitate not only human speech to astounding perfection but also a seemingly endless variety of other noises. This extreme imitative ability of certain groups poses a real evolutionary problem, since it appears not to be used at all except under conditions of domestication. In other words, it seems as if the bird is in some way 'pre-adapted' for the performance of dazzling feats of imitative virtuosity which conditions of life in the wild never require of it.

In the tropics, although there are many species of birds the song of which is doubtless just as territorial in function as is usual in the temperate regions, the ornithologist is also struck by the number of examples where song appears much less aggressive in intent and where its function is apparently as a social signal, for maintaining pair and family bonds and as part of the sexual display, rather than a territorial one. Moreover, it is perhaps significant that most of the outstanding vocal imitators are found among tropical or sub-tropical species. It is suggested that the extreme developments of the imitative ability occur where the main function of the song is to provide for social recognition and cohesion rather than for territorial defence. This seems to apply specially in the tropics.

In 1903 Waite⁷ described how two captive Australian magpies (*Gymnorhina tibicen*) learned to sing a fifteen-note melody, played to them on the flute, as an antiphonal duet. When the younger bird died the survivor resumed the performance of the whole; which it had never been heard to produce during the years when it had a companion. A rather similar case of the antiphonal division of a learned melody between a pet canary (*Serinus c. canarius*) and a captive bullfinch (*Pyrrhula pyrrhula*) was described in the same year by the famous musician Sir George Henschel⁸. Recently, Gwinner and Kneutgen⁹ described how, with two pairs of captive ravens (*Corvus corax*) and three pairs of the shama (*Copsychus mala-*

baricus), the males and females each had sounds or song elements which were principally, if not exclusively, their own private utterances and were not normally used by their mates. However, when the partners were absent, the remaining bird would use the sounds normally reserved for his partner, with the result that the said partner would return as quickly as possible as if called by name. (We have both experimental and field evidence for the same effect with *Laniarius aethiopicus major*.) Gwinner and Kneutgen find the method to be particularly effective if it is the male who is absent, since, they suggest, there is nothing more stimulating to a mated male than to hear its own repertoire repeated in its own territory. Thus, the vocalizations of these species appear to be used for securing the return of the desired partner. It seems from the work of Zur Strassen¹⁰ that, contrary to much previous supposition, parrots can also use their learnt vocalizations in a 'purposive' manner for securing food or other particular needs.

The study of the antiphonal singing of certain tropical birds, on which we have now been engaged for some years, is particularly relevant to these problems. Our investigations have been concerned with three widely separated groups of birds, one non-passerine and two passerine, namely, the barbets, *Trachyphonus* spp. (Capitonidae), fantail warblers of the genus *Cisticola* (Muscicapidae, sub-family Sylviinae) and shrikes of the genus *Laniarius* (Laniidae including Laniariidae). In all these groups one encounters species capable of a duetting in which the notes of the male and female are different—the sexes alternating to sing antiphonally but nevertheless with a very precise and exactly maintained time interval

between each contribution. One of us¹¹ has already published an account of the antiphonal singing of *Laniarius erythrogaster*, where the response time with which the female answers the male is of the order of 150 msec or less, with a standard deviation over a long series of 12.6 msec. Here it was suggested that it is the exact precision of timing of the answer of the second bird which is the most likely basis for the mutual recognition in dense foliage rather than any individual difference in tonal quality or structure of the notes—although this is not ruled out.

Since this work was published, Grimes¹² has obtained almost identical results with another species in West Africa—*Laniarius barbarus*.

However, from the point of view of the general problem already outlined here, it is the species that we are now mainly concerned with, namely, *Laniarius aethiopicus*—the tropical bou-bou shrike—which is providing most of the important results to date. Although a great deal remains to be done, a number of essential points already seem clear, and it is the object of the present article to outline the most relevant of them. In this species both male and female have a considerable vocabulary which it seems, they utilize so as to work out with practice a series of duet patterns by which, presumably, when the birds are no longer in sight of each other mutual recognition is still possible. This work is proceeding in the field in Kenya and Uganda, and in tropical aviaries at the Cambridge Sub-Department of Animal Behaviour. The following essential points seem to be clear:

(1) Although there may be periods of solitary 'practice' during the juvenile stage, the duet is worked out during

Fig. 1. *Laniarius aethiopicus sublaetis*. Vipingo, Kilifi, Kenya. December, 1954. *N.B.* All the illustrations are given at approximately scientific pitch (middle 'C' = 256 c/s). Unless otherwise stated, as here, all the figures refer to race *major*.

Fig. 2. *L. aethiopicus*. Dundori, Nakuru, Kenya, March 17, 1964

Fig. 3. *L. aethiopicus*. Kabale, Uganda, February 15, 1962

Fig. 4. *L. aethiopicus*. Meadow Point, Lake Nakuru, Kenya, March 17, 1964

Fig. 5. *L. aethiopicus*. Hippo Pool, Lake Nakuru, Kenya, March 17, 1964. Note that this is a rather more elaborate duet than the previous ones. The contribution of the two birds is not indicated in this case since it seemed to vary a good deal.

Fig. 6. *L. aethiopicus mossambicus*. San Martino, Mozambique Coast (C. Haagner). The timing in this example is very precise, but the bar length might vary between 0.75 and 1.5 sec.

Fig. 7. *L. aethiopicus mossambicus*. San Martino, Mozambique Coast (O. Haagner). This is a duet with a more complex time pattern. Bar length 1.5 sec.

Fig. 8. a-q. *L. aethiopicus*. Reed Inlet, Lake Nakuru, Kenya, September 5, 1963. The separate figures a-q show the 17 different duet patterns produced by a single pair of *L. ae. major* during the course of a single day. The last four patterns were transcribed in notation (ref. 12). All the rest were recorded directly on tape. All were presumed to be duets, but the distribution of the parts between 'X' and 'Y' is only inserted where the evidence is clear. The expression 'chatter scold' denotes a characteristic harsh pulsed sound of wide frequency distribution. The term 'snarl' is expressive of a common note, not markedly pulsed, but with the energy, though widely spread, showing a peak at the frequency indicated by the wavy line.

a long practice period (probably of many months) between two birds in their territory.

(2) These duets are composed of notes, the quality of which is determined, no doubt, by hereditary constitution; but the pitch, timing and phrasing of which can be varied very exactly by the singers as a result of this practice.

(3) For nearly every species so far examined it appears that: (a) Either sex can start and the other finish. (There is clear evidence for this in *Laniarius aethiopicus* and *L. funebris*. It is probably also true for *Cisticola hunteri* and *Cossypha heuglini*.) (b) Either bird can sing the whole pattern alone if the partner is absent (*L. aethiopicus* and *L. funebris*). (c) In *L. aethiopicus*, when the partner returns two birds can either duplicate in perfect time or (more usually) sing antiphonally again. Thus it appears that in the course of developing its elaborate duets each individual of the *L. aethiopicus* pair has, in fact, learned the contribution of the other member and its relation to the whole.

In *Laniarius aethiopicus* each pair in the wild may have a considerable number of alternative duet patterns. Consequently, while many of the simpler patterns may be very widespread in a given population, some are likely to

be peculiar to individual pairs. If this is correct, then the mate is that bird which can answer with the right pattern of notes in the right time. These vocalizations have, of course, been recorded by us and analysed by means of the sound spectrograph, but with this particular species the notes are of such a pure flute-like quality that they can be rendered satisfactorily in ordinary musical notation, and consequently this is the method we are adopting in the present report.

In those exceptional cases where, for one cause or another, tape recording was not possible, the songs were noted down by means of a specially adapted notation⁸, the pitch being determined by comparison with a chromatic pitch pipe. The illustrations very largely speak for themselves. Since it is usually impossible in the field to distinguish the sexes apart, the contributions of the two members of the pair are simply indicated as 'X' and 'Y' rather than by male and female signs. Thus, the first bird to be transcribed is labelled 'X' as the bird which, on that occasion, sings the first component of the duet pattern. The second contributor is then labelled 'Y'. Thus, if the sexes alternate their roles, 'X' will sometimes be the male and sometimes the female; and similarly

Fig. 9. *a* and *b*. *L. aethiopicus*. Lake Bunyoni, Kabale, Uganda, February 14, 1962. Fig. 9*a* represents a duet pattern heard as a very long, precisely timed series. During one considerable stretch of this series a third bird 'Z' joined in. It was far away from the others, but nevertheless inserted its single note remarkably accurately (Fig. 9*b*). It tended to intervene in every second duet of 'X' and 'Y'.

Fig. 10. *L. aethiopicus*. Dundori, Nakuru, Kenya, April 3, 1964. A remarkable trio. All three birds were in the same tree. Note that bird 'X' gave a D sharp every two seconds and bird 'Y' a D sharp every other two seconds while bird 'Z' gave a G sharp and an A natural every other two seconds in alternation.

with 'Y'. To date, rather more than 135 different duet patterns of *Laniarius aethiopicus major* have been recorded and analysed. A characteristic selection of these is here shown. Some races of *Laniarius aethiopicus* (for example, race *major*) appear to produce a greater variety of duet pattern and to be more flexible in their combinations; but this may merely be due to the fact that this is the race which it has so far been possible to examine most intensively. So far we have encountered one pair of birds in Nairobi which produced twelve different duet combinations, and another pair at Nakuru, Kenya, which produced seventeen different duet patterns in the course of a single day (Fig. 8).

Figs. 1-7 show a characteristic selection of duet patterns, proceeding from the rather simple to the more complex. Note also the way in which the total time taken by a duet can be varied considerably even by a single pair of birds more or less irrespective of the number of notes which it contains. Note, too, how the second bird may add or interpolate a single note within an already well-established pattern. Sometimes this note almost exactly duplicates one of the existing notes, in which case it can usually be distinguished only when the record is analysed by sound spectrograph. At other times it can be distinctly heard—as in Fig. 8*k*.

The 'musicality' of these songs strikes all who hear them. This is partly because of the purity of tone and the low pitch as compared with the songs of most birds. But in addition to this we find the birds using a familiar musical tonal system in a strikingly 'orthodox' manner. The implications of this are now being investigated.

With several of these birds which sing antiphonally, trio singing is sometimes observed. The meaning of this is at present quite obscure. It often recalls the well-known visiting of fulmar petrel (*Fulmarus glacialis*), the 'piping parties' of the oyster-catcher (*Haematopus ostralegus*) and the dance of the spur-winged lapwing (*Belonopterus chilensis cayennensis*) described by W. H. Hudson¹⁴. In more than one instance of trio singing in *L. aethiopicus* observed by us, besides the three birds part-taking, a fourth bird was observed standing silently by; possibly the mate of No. 3. Figs. 9 and 10 show examples of such trio singing in *L. aethiopicus major*. Trio singing is also very frequent in *Cossypha heuglini*, Heuglin's robin chat, which is also being studied in field and in aviary. An account of this will be reserved for later publication.

It is concluded that our observations so far give strong support to the suggestion put forward by Gwinner and Kneutgen, and also by Konrad Lorenz, that one of the major functions of the imitative ability of birds is to

establish and strengthen the individual pair bond. We suggest that this will be so particularly in those species where territorial aggressiveness is not very marked—as so often the case in the tropics. In *Laniarius aethiopicus* this ability enables each bird to learn the normal contribution of its mate as well as its own. It can thus use this appropriately for maintaining contact with the partner and recalling him or her when absent. If this is so, the extreme of apparently unused imitative ability in birds such as parrots and mynahs received a plausible explanation. It may well be that in the wild these birds use their powers for imitating the minute idiosyncrasy and inflexions of their partners or other members of the group. If this proved to be true, it is no longer necessary to suppose a mysterious 'pre-adaptation'.

Many, perhaps most, mammals recognize their associates primarily by smell and secondarily by sight. Voice and its recognition seem to come (with certain exceptions among them possibly the Canidae and some Ungulates) a long way behind in importance. With birds, creature of vision as they are and with the powers of olfaction greatly attenuated, audio-vocal recognition is probably paramount. But how did it come about that *Homo sapiens* so greatly outdistances his fellow Primates in his powers of using his auditory sense for social purposes?

We thank Mr. C. E. Cade, of Nairobi, for his pains taking work with hand-reared birds in the early stages of investigation. We also thank Mrs. Avril Royston, formerly of Sotik, now of Nakuru, Kenya, for her work in catching and hand-rearing birds—particularly shrikes. Without her expert help the aviary observations so essential to this work would have been impossible. We are also much indebted to Mr. Clem Haagner for allowing us to use some of his tape recordings of race *mossambicus*. Much of the cost of the work has been defrayed by grants from the Royal Society.

THE INTERNATIONAL BIOLOGICAL PROGRAMME*

By DR. E. B. WORTHINGTON

Scientific Director (Designate)

THE International Biological Programme is now well into its first year—the first of seven or eight. It is concerned with “the biological basis of productivity and human welfare”. It is divided into two phases: Phase I, which consists mainly of design and feasibility studies, to occupy most of 1965 and 1966; Phase II, the operational programme, to commence in 1967 and carry on for about five years. Beyond these simple facts I doubt if there are many people who know much about the Programme, for we have been so busy planning it that little thought has been given to advertising it.

The International Biological Programme is a programme which, because of the effects of various factors, particularly the climate, must extend over a number of years, since it is obvious that an investigation of growth in a summer such as we have had this year would be quite different from a similar study undertaken last year. It has, however, drawn some of its inspiration from the International Geophysical Year. Indeed, if one looks at the development of the sciences during the past few decades one is struck by the high peaks of achievement reached in international collaboration and also through international competition in the physical sciences. Research on the ionosphere, the atmosphere, and the geosphere has been greatly stimulated by organized activities—the International Polar Years, the International Geophysical Year and the International Years of the Quiet Sun which have developed one from the other. Programmes are going forward strongly, too, in connexion with the hydrosphere, as arranged by the Intergovernmental Oceanographic Commission and the International Hydrological Decade. But in such investigations the biosphere has been almost completely neglected. Yet on the natural resources of this Earth—especially the renewable ones which come from biological productivity—the future of mankind depends. They are much more important to most human beings than getting to the Moon or taking close-up photographs of Mars. One could even argue that it is more important to humankind to ensure a sustained yield of fish from the North Sea than to discover and extract the oil that may lie beneath it.

What do we mean by biology within the context of the International Biological Programme? To some, biology means the life sciences as opposed to the earth sciences; to some it stimulates thoughts of the inner workings of the cell; and to some perhaps, merely the facts of human reproduction. For the purposes of an International Biological Programme, I think the best definition is the biosphere, that is the living layer around the Earth, on land, in the waters and in the air.

This word biosphere, by the way, seems to present a problem in semantics. I have heard it explained by a television astronomer as a concentric region of the solar system, comprising the orbits of Venus, the Earth and Mars, where there is some reason to believe that life as we know it exists. I use it, however, as the layer which supports life in, on and around the Earth, for the International Biological Programme is likely to have little time or opportunity to extend its activities to other planets.

Some biologists are inclined to think that the International Biological Programme is rather a waste of effort and money. They argue that opportunities for the exchange of knowledge and ideas are not lacking, but are

almost overburdening, for international unions and associations exist in every branch of biology. From spring to autumn scarcely a week passes without some international biological congress, often several running contemporaneously, even in the same country. Is this not enough?

The counter argument is that we scientists concerned with environmental biology have to take but one look at our colleagues concerned with the physical environment to appreciate what a degree of organization can do. Few would deny that studies of this kind of biology, concerned with the organism in relation to its environment, which had such a splendid start in the past century, have been sadly overtaken in this century by studies in the physical sciences. In the long run, I believe that the International Biological Programme will be looked on as a major effort—and a successful one—to redress this balance. In doing so it will provide a part of the fundamental knowledge which to-day is so much needed so that biological science can be applied more effectively to the provision of human needs.

History

Before examining the content of the International Biological Programme we should consider how the idea came into being. British scientists have taken a prominent part in this. Sir Rudolph Peters some years ago, when president of the International Council of Scientific Unions (ICSU), took a major part in the conception of the International Biological Programme. Prof. H. W. Thompson of Oxford, the current president of ICSU, did a good job as midwife during the first International Biological Programme Assembly held in Paris last year. Prof. C. H. Waddington, as president of IUBS, has been a good doctor in the pre- and post-natal clinics; while the president, officers and secretariat of the Royal Society, by priming and holding the feeding-bottle, have enormously helped the infant's early growth.

How the ideas leading up to the International Biological Programme have fluctuated and developed has been related by Prof. Montalenti, the Italian geneticist who led much of the preparatory work. Initially, it was thought that the programme should concentrate on the human organism, and especially population dynamics and genetics. Later there was a body of opinion which thought it could involve itself best on the preservation and conservation of biological systems in different parts of the world, especially those which are most endangered by economic progress. Finally, these and other approaches have been brought together in such a way as to be of interest to a rather broad spectrum of biological scientists. The objective, as defined in 1964, is to ensure a world-wide study of: (a) organic production on the land, in fresh waters, and in the seas, and the potentialities and uses of new as well as of existing natural resources; (b) human adaptability to changing conditions. The programme should not range through the entire field of biology but should be limited to basic biological studies, related to productivity and human welfare, which will benefit from international collaboration, and are urgent because of the rapid rate of the changes taking place in all environments throughout the world.

Thus, of two major problems now facing the human species on Earth—of controlling his rate of reproduction

* Substance of an Evening Discourse delivered on September 3 at the meeting in Cambridge of the British Association for the Advancement of Science.

and of increasing the biological product on which he subsists—the International Biological Programme is concerned with the second. The advances in techniques to control reproduction which have been produced in the past decade have reached a point at which there is more need for sociologists to apply them than for biologists to invent new ones. Yet the attributes and potentialities of man are by no means left out of the programme, as I will explain.

Principles

The programme is based on a number of principles. First, it is a directional and a selected programme. It is not a free-for-all, nor is all research bearing on productivity and human adaptability automatically incorporated into it. The initials IBP can be regarded, if you like, as a kind of status symbol, and to ensure that this is not misused we have a sifting arrangement for projects at the national level and later at international level before admission into the programme. The tag of IBP does not, of course, mean that the project is necessarily good science, nor that other work on biological productivity conducted outside IBP is not good science. It merely implies that those immediately concerned with IBP agree that the project fits in and is likely to advance materially the objects of the programme.

Secondly, the programme is concerned throughout with the fundamental approach to research. It starts from the premise that the applied sciences of biological production, such as agriculture, forestry, fisheries, have in recent decades gone striding ahead more quickly than the fundamental understanding of the causes of productivity. Similarly, the sciences of man, medicine and some of the applied social sciences, have in some ways out-paced fundamental understanding of mankind and the differences between one man and another. The International Biological Programme is an opportunity to restore the balance and to provide new organized knowledge as a springboard for the technologies to take further plunges into progress.

Thirdly, the International Biological Programme is urgent. This is not only because of the steady growth of the pressure of human populations on renewable resources, but also because many of the situations in the world, both biological and human, are changing so rapidly that they will soon cease to exist. The International Biological Programme is not a preservationist body, for our approach is dynamic not static, conservation rather than preservation; but the perpetuation of sample biological systems for future biologists to study is definitely among its objectives.

Fourthly, and this could perhaps almost go without saying, the International Biological Programme is limited to research which could benefit from international co-operation. There are some scientists, and great ones at that, who do not readily co-operate with others and whose special attributes lead them to penetrate deeply on a narrow front the unknown, behind locked doors so to speak, rather than, by a sharing of knowledge, to advance with others along a broad one. The International Biological Programme is clearly not designed for the isolationist researcher, although his findings might well be picked up and developed as a Programme project.

Divisions of the Programme

In order to get to grips with what inevitably is a very large content, the International Biological Programme is divided into seven sections. One of the first and most obvious divisions was into the biological communities of the land, of fresh waters, and of the sea, because terrestrial ecology, limnology, and oceanography have each developed their own discipline of research, although biological energy often flows from one to another. These three sections are known by their initials; PT for Productivity

of Terrestrial Communities; PF for Productivity of Freshwater Communities; PM for Productivity of Marine Communities.

All three have their problems of conservation, include the definition, description and management of prescribed areas or samples of living communities. The problem of conservation on the land are more extensive and generally more complex than those of the waters. They include such concepts as national parks, nature reserves and sites of special scientific interest. Therefore, there is a special section of IBP labelled CT for Conservation of Terrestrial Communities. Each of the three, moreover, presents different facets of the processes of production—photosynthesis (utilization of solar energy) and the nitrogen cycle—this section is called Production Processes (P). Each of the three may reveal new resources of value to mankind or new methods applicable to the use and conservation of resources, which require fundamental study; this will be carried out within the section named UM for Use and Management of biological resources. Finally, the human problems, which bring in another series of disciplines, notably physiology and anthropology, will be studied within the Section of HA, Human Adaptability. This makes seven: PT, PP, CT, PF, PM, HA and UM.

Each of these sections is headed by an international convenor and sectional committee, and is busy in producing a five-year programme of its own. Two of the convenors are British—Mr. Max Nicholson of CT and Prof. J. S. Weiner of HA. The seven sections are, of course, closely related to each other, but also to other programmes going on during the same period, for example PF to the International Hydrological Decade.

IBP consists of the sum of its parts, not only in the sense of containing seven different programmes, but also in the sense that the bulk of the research will be undertaken and financed nationally, not internationally. Many countries are at present busy preparing their national programmes, and of these one of the most advanced that for the United Kingdom, now published by the Royal Society.

Examples of Research

Let us take a few examples of the kind of work which IBP will contain, and think especially of the British contribution. Although a great deal has yet to be learned about our own biological communities and our own people, some of the thinking has been on the lines that we should use the knowledge and abilities of a good many scientists overseas, where ignorance about biological productivity is still very great. Thus the U.K. programme in its PP section aims to establish two bases for IBP work in the warmer regions overseas, in co-operation, of course, with the countries concerned. One of these is likely to be in a savannah country, at the Cambridge Nuffield Unit of Tropical Animal Ecology, situated in the Queen Elizabeth Park in Uganda; another at a site yet to be determined in an area of tropical rain forest. At these bases, in co-operation with local scientists, it is hoped to undertake investigations of productivity in depth—primary production of the trees, shrubs, grasses and herbs, secondary by herbivorous mammals and insects, tertiary by predators and parasites.

It is hoped to quantify as well as qualify each link in the food chain so as to obtain data to compare production in the wild with production from the tame, for example where domestic animals and plants have been established on land used for agriculture.

Passing to another section, namely CT, it is pleasing to report that something has been actually achieved. In the spring of 1964 and again in 1965, expeditions went from Great Britain to the desert lands of Jordan, and made a survey especially of the Azraq Oasis and its environs, to the east of Amman. This has resulted in several things: a useful IBP booklet entitled *An*

approach to the Rapid Description and Mapping of Biological Habitats, and more important, in detailed commendations about the creation of national parks in Jordan. Further preparatory work has been based on the Azraq Oasis where the park headquarters and garden are now established with American aid. Within a week or two, two experienced members of the Nature Conservancy's staff are going there to prepare a management plan, applying the experience in management of wild areas gained in this country. Meanwhile, in August 1964, M. The King of Jordan publicly announced that he will set up the Azraq National Park, and also that Jordan will participate in the IBP by establishing at the Park's centre an institute for biological and human investigations in desert and oasis conditions. This indeed will make a useful counterpart to the proposed IBP bases in savannah and rain forest to which I have already referred.

From the PF section I will draw two examples of British initiative: one is an intensive study of the biological productivity of a reach of the Thames, organized from the University of Reading. This is dealing with primary and secondary production and will include studies on the feeding and population dynamics of a considerable number of fish species. It will fill a major gap in our knowledge of British fresh waters, for most intensive work has been devoted to lakes and very little to rivers. The other example relates to research in tropical lakes. In terms of food supplies through fisheries, and water supplies for irrigated agriculture, they are of much greater importance to the world than the little lakes in our own country. So the programme includes the establishment, based on a grant from Britain, of a team of limnologists for work in the tropics, especially Africa. This takes advantage of the fact that we happen to have in Britain a rather particular expertise in tropical lakes.

During the present planning phase each of the seven sections has already held, or has arranged, a number of symposia consisting of selected specialists from all over the world to discuss methods of research in particular spheres and to prepare handbooks. The object here is not to 'straight-jacket' the methods in use in IBP, for field biology is at present advancing very rapidly through the development of old methods and the devising of new ones; but it is to agree on those proved methods which can be advised for general use throughout the world and can be relied on to produce comparable results. A good example was a symposium held in Aberdeen and Cambridge in September concerning research on large herbivorous mammals. In Australia, studies of kangaroos and introduced sheep suggest that the former may be more effective converters of grass into meat than the latter; if only kangaroos produced wool instead of hair, they might be the basis of Australian prosperity. In Africa there are indications that the broad spectrum of indigenous African mammals, such as giraffe, antelopes, buffalo and wart hog, may be better agents of secondary production of meat than the exotic cattle, sheep and goats which have replaced them in many areas and are apt to depress the yield of the habitat. In Scotland we have the Island of Rhum, where management of red deer by the Nature Conservancy has resulted in more venison coming off the island than mutton under the former agricultural management and at the same time it seems as though the level of primary production of the vegetation has been raised. This symposium brought experiences of this sort together and advised on methods for future work under IBP from the three points of view—the ecological, the physiological and the pathological.

Another example I want to give is one with which I am personally involved just at present, namely research on large man-made lakes. The basic reason for creating these is generally for hydroelectric power: for example, at Kariba, Volta and Kainji in Africa, Brokopondo in Surinam, and a number of large impoundments in North America. Sometimes water conservation for irrigation

is equally or more important, as in the Aswan High Dam in Egypt. But the influence of these great sheets of water will extend not only to producing power and water but also to many other human needs, and has a profound bearing on the biology of large regions. Anyone familiar with Africa, for example, will realize the fundamental influence of the great natural lakes on climate, vegetation, fisheries, water supply for man and stock, transport, sites for urban development, and the rest. Since the period of IBP happens to coincide with the period of constructing several new great impoundments and of the biological changes consequent on several of those already completed, their study will take quite a significant place in the programme. Here again, it is good to note that Britain has taken an initiative, and as I speak a group of eight scientists drawn from Liverpool and other universities in Britain and Nigeria, and supported financially by the Ministry of Overseas Development, are undertaking a preliminary investigation of the part of the River Niger where Mungo Park met his end in 1806, the reaches which, in a year or more, will form a five-hundred square mile lake impounded by the dam at Kainji. The group has now been joined by several American and African sociologists who are extending the aquatic study to the 50,000 or so people now living below the future water-level. Under the leadership of local people, assisted by scientists from outside, and with funds which we hope will be provided by the special fund of the United Nations, it is hoped to establish a co-ordinated programme of study on these great impoundments.

I have been speaking mainly about the purely biological aspects of IBP, but the section on human adaptability has so far been quite one of the most active. It brings in a lot of scientists in the spheres of medicine and of physical anthropology, and its programme is designed rather differently from some of the other sections. It is wide and comprehensive, divided into a large number of headings and subheadings. Research topics include environmental physiology, including tolerance of different human groups to cold, heat, and high altitude; fitness, growth and physique, which, incidentally, will include a survey of highly fit athletes; the genetics of populations, with international data centres to be developed on existing national ones such as the blood-group centre of the Medical Research Council in London; and lastly health, nutritional and epidemiological topics. Clearly a lot of this work will need to be done by groups of research workers travelling with their equipment to study communities in their natural environments. This involves mounting a good many quite complex expeditions to remote places. British workers under IBP/HA expect, for example, to work this autumn on the Hazda tribe around Lake Eyasi in Tanzania and the people of Bhutan in the very high Himalayas.

Organization

There is a school of scientific thought that resents all forms of direction or organization. Science is free: give us the funds and let us go unfettered in any direction where research leads, and we will show results. Good scientists should not become administrators; any who do so are so much loss to science. This is an attitude which some of us associate with the older universities, but it is quite widespread, within Government scientific service as well as outside it. I met it strongly expressed when discussing IBP recently in Uganda. Now this libertine approach to science does not face the realities of how the funds and facilities for research are to be produced, how the results are to be discussed and published, or how those results which have an element of application in them might be turned to practical use. Nevertheless, it is an attitude with which I personally, and many others who are concerned with IBP, have a good deal of sympathy. We have been influenced by it in thinking up the organization necessary for IBP, at least to the extent that we have

devised this as lightly as possible. We are trying to build a simple structure from the foundations and to make the roof no heavier than is necessary to protect those inside from the weather.

Starting from the top there is ICSU which has set up the Special Committee for the International Biological Programme (SCIBP), comparable with its scientific committees for Oceanic Research (SCOR) and Antarctic Research (SCAR). SCIBP is a democratic organization which holds a general assembly about every two years. It has a Swiss president, Prof. Jean Baer, vice-presidents from Italy, Poland, the United States and Great Britain, and a number of other members, some representing the main international unions in the biological sciences and some drawn from the different bio-geographical regions of the world. It includes also the seven international conveners of the sections of IBP. Unesco, FAO, WHO, SCOR, and SCAR have representatives on it. Each of the conveners has also his sectional committee of specialist members drawn from all over the world.

The central office for IBP is at 7 Marylebone Road, Regent's Park, London, in accommodation generously provided and furnished by the Government and the Royal Society. Each of the seven international conveners has his own office, although only four of them as yet have whole-time staff.

Publications of IBP are so far very few: a journal called *IBP News* was started in October 1964, and so far three numbers have been published. We are also starting a series of handbooks, and the first of these, being a general guide to the activities of HA section, has just gone to press.

The central funds, for running the offices and holding meetings and for publications, come from national dues paid in by each participating country. These are on a rather modest scale and in fact are at present insufficient. I am glad to say they are augmented by grants and loans from ICSU and Unesco, and a particularly generous grant recently made by the U.S. National Academy of Sciences. It is hoped that other countries will follow this excellent example.

The finance I have spoken of is concerned only with the organizational framework and, by international standards, is quite small. The cost of the actual research undertaken under the auspices of IBP in all parts of the world will naturally be quite large if the programme is to be at all worth while. As yet it is impossible to say how much it may cost, because very few national programmes have yet been prepared in detail although a number are in active preparation. If we take the British programme as a model, and if some twenty major nations have comparable programmes and twenty or thirty others prepare smaller programmes, the total is bound to run to several million pounds. The finance for national programmes will of course be provided nationally: in this first year of design and feasibility studies, the British Treasury has provided some £80,000 specially for IBP; added to the normal votes for the Royal Society and the Nature Conservancy. This will enable some appointments to be made and some research of a trial nature to be started. A number of other

countries have acted somewhat similarly. Czechoslovakia for example, in addition to financing its own planning phase, has provided from its own funds the office and staff for one of the international conveners, Prof. Malek who is based in Prague.

In order to plan and carry out national programmes many countries are setting up their own national committees, often with sub-committees equivalent to the international sectional committees of SCIBP. Thus the United Kingdom, through its committee structure which operates under the patronage of the Royal Society, brings about 150 British scientists into the active planning stage. The United States now has a national committee and Dr. Roger Revelle, Poland one under Prof. Petruszewicz, Japan not only has a national committee but has already submitted a programme. I believe that before long a major problem of SCIBP and of its Central Office will be not so much to get IBP in motion which has been a preoccupation up until now, but to prevent it running away from itself by becoming too large and unmanageable.

Conclusion

The gestation period of the Programme has been long, but recent progress is at a much greater rate than we have dared to hope a couple of years ago, for the world needs a IBP. What, then, is the philosophy behind it? What is the driving force that causes many busy people about the world to devote their time and energy to helping it on? I suggest it is a spirit of service to our fellow men and to the other animals and plants that make up the very varied living communities of the Earth. Even in these days of rather selfish approach to living, apparent in the political, commercial and even scientific spheres, I suppose there is some feeling of service in all of us, even if it is only an instinct towards conserving the race, after conserving the individual. Here in IBP is the opportunity for very many biologists, whose efforts may have been not perhaps of very high value to others, to bring their researches together to focus them and to make them more useful. Here in IBP is the opportunity of showing the world the value of field biology as well as laboratory biology. New resources will undoubtedly be discovered, and so also will be the aesthetic as well as the scientific and economic value of plants and animals in their natural and also in their man-made environments.

An important part of the service IBP hopes to render will be to ensure that at least samples of these wonderful creations of evolution, so different and yet so similar in the several bio-geographical zones, will continue and flourish for subsequent generations of humans to appreciate and use. Nor should we forget the many and diverse races of man himself, with their separate and particular attributes. Unless we understand these matters and use our understanding to plan the future, they will go down before the axe and fire, the bulldozer or the hypodermic needle. This marvellous biological differentiation on the Earth would then tend towards dull uniformity and even obliteration.

OBITUARIES

Dr. L. H. Gray, F.R.S.

DR. LOUIS HAROLD GRAY, first director of the British Empire Cancer Campaign Research Unit in Radiobiology, died suddenly on July 9, 1965. He was fifty-nine.

Hal Gray, as he was known to his friends the world over, enjoyed a unique position in his chosen subject. Radiobiology calls for a wide-ranging mind, able to grasp the fundamental concepts of physics, chemistry, biology and medicine. To the end of his life, Gray retained an

intellectual vigour which enabled him to seize the essentials of a new scientific discipline, and relate them to the existing body of knowledge.

Educated at Christ's Hospital, Horsham, to which he won a scholarship, he soon displayed an outstanding aptitude for science and mathematics. At school he was much influenced by "Chas." Browne, then head of science, who educated his pupils on the principle that it is better to do an experiment than to look up the answer in a

ok. This 'do it yourself' approach was to remain a characteristic feature of Gray's work throughout his life. From school, he won an Exhibition at Trinity College, Cambridge, and two years later took Part I of the Tripos in physics, chemistry, mathematics and mineralogy, and as awarded first-class honours. Proceeding to Part II in physics, he again achieved a first and was able to commence research at the Cavendish Laboratory during an exciting period of Rutherford's professorship. In 1930 he took his Ph.D. and received a Fellowship at Trinity.

His work at this period was concerned with the scattering and absorption of γ -rays, and in his first publication (1929) he enunciated the cavity ionization principle, which had previously been described by Bragg in 1912, although Bragg's work was unknown to Gray at the time. His theory, which is fundamental to γ -ray dosimetry, became known as the Bragg-Gray principle.

Despite his success in pure physics, he began to find the subject not completely satisfying, and he felt the need to do something of more obvious value for his fellow men. An offer to come to Mount Vernon Hospital as physicist appealed very strongly to him and he took up the position in 1933. Although his work at Mount Vernon was primarily concerned with the accurate measurement of ionizing radiation, he began to take an interest in biological problems under the guidance of that remarkable man, Dr. J. C. Mottram. Before leaving Cambridge, he had begun a fruitful collaboration with F. G. Spear, of the Strangeways Laboratory, studying the effect of neutrons on hen eggs. The neutron source available to them proved to be too weak, Gray, with the collaboration of John Read, built a highly effective neutron generator for an outlay of some £600, with which the first biological results were obtained in 1938. At this time, Read and Gray suggested a unit, the Energy Unit, which was applicable to all forms of ionizing radiation and was almost identical with the rad unit adopted by the International Commission on Radiological Units and Measurements some fifteen years later. During the Second World War, when he was working alone, he began to consider the dynamics of cellular population changes underlying the gross changes in behaviour of a bean root following irradiation, thus anticipating one of the focal points of interest in modern radiobiology.

In 1946 Gray went to the Medical Research Council Radiotherapeutic Research Unit, as senior physicist, and in 1950 was promoted to deputy director. Here, he had overall responsibility for building up several teams to carry out ambitious projects in radiation research, the construction of a cyclotron, the development of radioisotopes in research, and general radiobiology. This heavy administrative load left little time for his personal researches, but his wise choice of staff is reflected in the advances in radiobiology made by his group. The classic investigations of Howard and Pelc on the relation of DNA synthesis to the mitotic cycle, and of Miss Alper on bacteriophage, date from this period.

In 1952 Dr. Gray initiated a programme of research on the oxygen effect in radiobiology, and its relation to radiotherapy. Those who had the good fortune to work under Hal Gray at that time will always remember his boyish and generous enthusiasm, which infected all those near to him. Within six months the main outlines of the picture had been established—a picture which still inspires much of present research in radiobiology. It was characteristic of Hal's disarming modesty that his collaborators had the greatest difficulty in persuading him to be the first author of the paper which recorded this work.

In 1953 Gray resigned his position at Hammersmith, following disagreements on scientific policy. Thanks very largely to the good offices of the late Lord Horder, who placed great faith in Gray, the British Empire Cancer Campaign undertook to finance a new Unit at Mount

Vernon, where he would be director with freedom to pursue his own lines of research.

With considerable foresight, Gray planned the use of a linear accelerator for the development of pulse radiolysis methods, in collaboration with J. W. Boag, a technique which has already revolutionized radiation chemistry. At the same time, he gathered around him a small group whose basic training lay in physics, chemistry, biochemistry, biology and medicine, since he believed strongly that collaborative studies by such a group offered the best hope for advance in an inter-disciplinary field. It was also a great delight to him to return to experimental work, which he did with undiminished energy, planning experiments which made few concessions to human requirements for sleep and food.

He had no love of committees, but he bravely accepted the administrative burdens which were placed on him. His work for the International Commission on Radiological Units will be particularly remembered, and the personal effort which he put in as president of the second International Congress of Radiation Research had a lot to do with the acknowledged success of that meeting.

Gray received many honours in recognition of his work, but two he prized highly were American awards, the Judd Award in 1954 and the Bertner Foundation Award in 1964. He was elected Fellow of the Royal Society in 1961 and received an Honorary D.Sc. at Leeds in 1962.

No catalogue of publications or prizes gives a true picture of Hal Gray's contribution to radiobiology. He delighted in helping other workers, particularly the younger ones, and he never grudged the time devoted to giving help and advice. Even an anonymous referee's comment would engage the whole of his great powers of critical appraisal and constructive comment. Varied and remarkable as his contributions were, it is certain that he will be remembered by those who knew him, not only as a great scientist, but also as a great man.

O. C. A. SCOTT

Dr. O. S. Sinnatt

DR. OLIVER STURDY SINNATT, professor of aeronautical science in the Royal Air Force College, Cranwell, from 1920 until 1940, died on May 28, 1965, at the age of eighty-two. Dr. Sinnatt was born in Liverpool on September 6, 1882, and educated at the College of Technology, Manchester, and the Owens College (later University of Manchester). He graduated B.Sc. in 1904, M.Sc. in 1907, D.Sc. (London) in 1915, and was elected Associate Fellow of the Royal Aeronautical Society in October 1924. After a year as master of engineering at the Carpenters' Technical Institute, Stratford, he joined the staff of King's College, London, in 1905 as a demonstrator, becoming a senior demonstrator and then a lecturer in the Department of Mechanical Engineering.

During the early part of the First World War he held various posts with the University of London Officers' Training Corps; for a period he was in charge of the Training Camp, Perivale. He was afterwards transferred to the London Regiment and posted to France early in 1917, rising to be second in command of the 2/2 Battalion of that Regiment.

He was severely wounded at Poelcappelle in 1917 and awarded the Military Cross in 1918. He joined the Air Ministry as a technical officer (Instrument Section) in 1918. He was appointed professor of aeronautical science at the Cadet College, Cranwell, in 1920.

In 1940, Dr. Sinnatt was appointed to the School of Aeronautical Engineering, Henlow, as senior education officer, where he remained until his retirement in 1942.

In 1920 he married Marjorie Helen, the only daughter of the late W. R. Randall, by whom he had two sons, the elder of whom was killed in action in 1944.

C. E. P. SUTTLE

NEWS and VIEWS

Director of Building Research, Ministry of Technology :
Dr. Frederick Measham Lea, C.B., C.B.E.

DR. F. M. LEA relinquishes his duties as director of building research in the Ministry of Technology on December 31, having reached retirement age. During his twenty-year tenure, the work of the Building Research Station has been greatly extended in scope, now ranging from research on the use of materials to structures, soil mechanics, heating, ventilating, lighting and acoustics, mechanical plant for building, operational and economics research and studies of user needs. Although often accused of technological backwardness, the industry has, in fact, made very rapid application of much of the work of the Station, particularly in the newer fields of research on mechanical plant and on costs and economics. In addition to this national activity, Dr. Lea has taken an active part in international collaboration in building research and he has served as president or as a member of council of most of the organizations working in this field. His early work at the Station, before appointment as director, was on the chemistry of cement and concrete and he has throughout retained a special interest in this field. It has attracted to him a number of awards, culminating in the Walter C. Voss Award of the American Society for Testing Materials, in 1963. His text-book *Chemistry of Cement and Concrete* is an established source of reference. He became a Fellow of the Royal Institute of Chemistry in 1936. He was appointed O.B.E. in 1944, C.B.E. in 1952 and C.B. in 1960, elected an Honorary Associate of the Royal Institute of British Architects in 1947 and an Honorary Fellow of the Institute of Builders in 1965.

Dr. J. C. Weston

DR. J. C. WESTON has been appointed director of the Ministry of Technology's Building Research Station at Garston, Watford, Hertfordshire, in succession to Dr. Lea. The appointment takes effect from January 1, 1966. Dr. Weston joined the Building Research Station in 1947 as a principal scientific officer, and was promoted to senior principal scientific officer in 1953. His concern was with building production methods and costs. Since 1959 Dr. Weston has been, as a deputy chief scientific officer, group head of the Station's Building Operations and Economics, User Requirements and Mathematical Services Divisions. He has been on secondment to the National Building Agency as chief executive of the Operational Division since June 1964. Dr. Weston was educated at Nottingham and obtained his degree at London and his Ph.D. for work on temperature changes accompanying magnetization processes in ferromagnetic substances. During and immediately after the Second World War, Dr. Weston was with the Admiralty Scientific Service. He was engaged in work on torpedoes and mine detection. This was followed by a year at The Plessey Company, Ltd., where he was responsible for the Physics Research Laboratory.

Director of the Scottish Plant Breeding Station :
Dr. J. W. Gregor, C.B.E.

DR. J. W. GREGOR retired on September 30 from the post of director of the Scottish Plant Breeding Station, Pentlandsfield, Roslin, Midlothian. After taking his Ph.D. at the University of Edinburgh in 1925 he joined the staff of the Station as chief assistant. In 1939 he was awarded a D.Sc. and was appointed director in 1950. He was made a Fellow of the Royal Society of Edinburgh in 1957 and was awarded a C.B.E. in 1961. Internationally known for his experiments on the genetics of

wild populations of *Plantago maritima*, he endeavoured to show the agricultural significance of his genealogical studies by relating them to pasture improvement in the Scottish hills. Always interested in the nomenclature of plants, he has made a number of contributions to the literature on ecotypic differentiation and the recognition of intra-specific variation in plants. Among many consultative groups on which he served was the International Commission for the Nomenclature of Cultivated Plants which produced the *International Code of Nomenclature*. Dr. Gregor has been succeeded by Mr. N. W. Simmonds

Mr. N. W. Simmonds

MR. N. W. SIMMONDS, head of the Department of Potato Genetics at the John Innes Institute, Hertford, has been appointed to the post of director of the Scottish Plant Breeding Station, in succession to Dr. J. W. Gregor. Mr. Simmonds was educated at Whitgift and Downing College, Cambridge, and then went to the Imperial College of Tropical Agriculture, Trinidad, in 1944 under a Colonial scholarship. After holding lectureship in botany at the Imperial College of Tropical Agriculture, Trinidad, he became senior cytogeneticist in the Banana Research Scheme and Regional Research Centre: a new tetraploid variety of banana was produced by the Scheme during his tenure of the post. In more recent years he has been consultant in sugar cane breeding in the West Indies. He returned to Britain in 1959 to become head of the Department of Potato Genetics at the John Innes Institute. Mr. Simmonds's botanical and plant-breeding investigations have taken him on extensive travels in Europe, Asia, Africa and America, and, while his main interests lie in the cytogenetics and evolution of crop plants (especially of bananas and potatoes), he has also published widely in the fields of ethnobotany, systematics and phenol biochemistry.

Psychology in the University of Reading :
Prof. Magdalen D. Vernon

THE retirement of Prof. M. D. Vernon from the chair of psychology in the University of Reading constitutes a landmark not only in her own working life, but in the development of the subject in Britain. She started work in Sir Frederic Bartlett's laboratory at Cambridge in 1921 as an Industrial Health Research Board investigator at the beginning of the remarkable period of progress there between the two Wars. She remained—later as a Medical Research Council staff member—until 1946, when the late Prof. A. W. P. Wolters secured her services as a lecturer at Reading. Appointed senior lecturer in 1955 and reader in 1956, she succeeded Prof. R. C. Oldfield in the chair in that year. Her massive contributions to the study of visual perception and especially of the processes involved in reading, both in experimental papers and in books such as *Visual Perception*, had already earned her an international reputation before she went to Reading. During her twenty years there that reputation has much increased, while her work in other fields, such as the motivation of children, has widened its basis. Her unfailingly high standards in research and in teaching have been a spur to her colleagues and students alike, and if many perhaps have found them difficult to emulate, much excellent work and an acknowledged distinction have been their fruit. Prof. Vernon's astringent good sense on academic and other committees has always been effective and deeply appreciated by her colleagues. Her period at Reading has spanned a time of very considerable expansion of the subject, with a large increase

student numbers and in research activities. As elsewhere, this has entailed a long struggle with the difficulties of inadequate accommodation and staff recruitment. But her admirable management and persistent advocacy leave the Department with a greatly enhanced reputation, and she is well poised for the further developments which may confidently be expected under her successor, Dr. M. Treisman (see *Nature*, 207, 689; 1965).

Discoverer of Nickel: Axel Fredrick Cronstedt

AXEL FREDRICK CRONSTEDT, the Swedish chemist and mineralogist, who died on August 17, 1765, is remembered not only for his discovery of nickel but also for his researches and writings. Though a member of the Stockholm Academy of Sciences, he had no university training; for, as a student at Uppsala, lack of finances meant abandoning his academic career to take a post as metallurgist in the Swedish Department of Mines. Yet his proved beneficial both to him and to his country. Georg Brandt coached Cronstedt in the techniques of assaying. In 1751 Cronstedt came across a new mineral from a cobalt mine, which at first was thought to contain copper, yet which yielded none by displacement from its solutions. The mineral, now known as niccolite, or nickel arsenide, formed green crystals on weathering; it was from these that Cronstedt prepared an oxide which on reduction with charcoal gave a new metal. Only in 1754 did Cronstedt christen it nickel, and describe the silver-white and feebly magnetic regulus to the Stockholm Academy. Cronstedt noted the brown borax bead, the blue solution formed with ammonia, and the close resemblance to cobalt. Chemists in France in particular refused to accept the new metal until Torbern Bergman, in 1774, added further evidence by preparing a specimen of it free from the cobalt, arsenic and iron which had contaminated Cronstedt's first specimen. In the history of chemistry and metallurgy Cronstedt's name appears frequently in connexions other than nickel, being listed with platinum, iron ores and zinc extraction—a field in which Cronstedt collaborated with Rinman, whose name remains in 'Rinman's Green'. Cronstedt won a niche even if only for his *System of Mineralogy* translated into several languages.

Political and Economic Planning

THE annual report of Political and Economic Planning (P.E.P.) outlines the current research programme which, during 1964–65, focused on problems of planning and policy-making in economic policy, Government, management, social issues and international affairs (Pp. 12. London: Political and Economic Planning, 1965). The Social and Economic Archives Committee has entrusted to P.E.P. the establishment of a Survey Archives Centre in Britain; for an initial period of two years P.E.P. will collect and disseminate information about survey data held, and surveys planned by university departments, research institutes, market research and commercial organizations and other relevant problems. During the year, a study of the effects of imprisonment of a man on his wife and dependants was published under the title *Prisoners and their Families* (see p. 216 of this issue). A survey of East African students in Britain was also completed during the year and published under the title *New Commonwealth Students in Britain—with Special Reference to Students from East Africa*. Since 1931, P.E.P. has organized 500 broadsheets and 50 books; a list of publications issued during 1963–65 is appended to the annual report.

Energy Forecasts for Britain

MR. D. G. TIPPING in the *Westminster Bank Review* for August 1965 questions the forecast of energy demand for 1980 of 450 million coal equivalent tons as too high,

since it is based on the assumption of a 4 per cent growth in the economy. He suggests that a more realistic range of expectation for 1980 would be 400–420 million tons, but he does not think that Britain is likely to be faced with a sudden critical shortage of energy brought about by unexpected changes in demand. He considers that the output of 200 million tons of coal per annum advocated by the coal industry is unrealistic, and points out that the demand for coal from the gas industry is likely eventually to fall to zero. The one market for coal which is likely to grow considerably is for the generation of electricity, and the main uncertainties here are the proportion of future demand to be met by nuclear power and the balance to be struck between the conventional fuels. There seem to be three major ways in which the coal industry could be helped to play its part in a cheap energy policy: through capital reorganization, apportionment of social costs (which lie at the core of the problem), and through the pricing system. Mr. Tipping insists that the State and not the consumers should bear the burden of interest on over-capitalization of some parts of the industry. Social costs should be borne by society and also a more rational pricing policy should be introduced. Any rational pricing system is logically prior to a rational target. He points out that we must plan not only to minimize any error but also to introduce sufficient flexibility to overcome the effects of error. There is already considerable spare primary capacity because the coal is accessible and merely needs the men and machines to get it. We are unaware, however, of the physical and economic possibilities of mothballing pits, or of the extent to which the present surplus capacity of 40 million tons would match the capacity of loss-making pits which one would like to close.

Utopia Reviewed

THE Spring, 1965, issue of *Daedalus*, the journal of the American Academy of Arts and Sciences, consists of a series of essays on various aspects of Utopia by writers who if not American born are, with two exceptions, working in the United States. Some, like Lewis Mumford's "Utopia, the City and the Machine", Prof. F. E. Manuel's "Toward a Psychological History of Utopias", Prof. Northrop Frye's "Varieties of Literary Utopias" and Judith Shklar's "The Political Theory of Utopia", have a certain historical bias. Others, including two at least of those already mentioned, are more concerned with the social implications, for example, Prof. C. Brinton's "Utopia and Democracy", Prof. A. B. Ulam's "Socialism and Utopia", F. Bloch-Lainé's "The Utility of Utopias for Reformers", Bertrand de Jouvenal's "Utopia for Practical Purposes" and J. R. Pierce's "Communications Technology and the Future". These, and also Prof. P. B. Sears's "Utopia and the Living Landscape" and Prof. J. M. Smith's "Eugenics and Utopia", may appropriately be read in conjunction with Jacques Ellul's recent book *The Technological Society*, to the fatalism of which some of the essays apply a slight corrective. Not even the more historical essays, however, refer to Marie Louise Berneri's scholarly work *Journey Through Utopia*, published posthumously in 1950, to which Mumford himself paid a generous tribute at the time. Prof. Frye, in fact, provides no references at all and generally, in contrast to Mari Berneri's book, the bibliographical side of the essays is weak. The titles of such essays as those of de Jouvenal, Sears, Smith and Pierce indicate their topical character, and perhaps the most optimistic are those of Prof. G. Kater on "Utopia and the Good Life" and Prof. Maren Lockwood on "The Experimental Utopia in America": both of these essays, incidentally, are well provided with references. While Mumford himself has not lost the optimism that marks his well-known trilogy, in the essay in *Daedalus* he accepts much of Ellul's position as to the dominance of the machine and points out that we can no longer think of the components of technology as additive.

We must face the implications of an articulated totalitarian system of which the machine is god and must recognize that our present scientific methodology is inadequate to deal with every aspect of human experience.

Social Implications of Automation

DR. A. HOVNE, in a recent issue of *Impact of Science on Society* (15, No. 1; 1965), discusses some social implications of automation, including the reasons which are likely to be decisive for the introduction of automation and why a new technique may not be adopted. After considering the unemployment aspects, he deals with the implications for four selected aspects of social life; for work in automated enterprises; for their organization; for the organization of Government. There are also certain broad choices to be made, particularly those relating to the place of work in the life of men, mobility in employment, the content of education, and to study as work. The two Cantor Lectures given to the Royal Society of Arts last March by T. R. Thompson and now published in the *Journal of the Royal Society of Arts* for August 1965 also deal with automation. The first of these lectures considers the economic problems of introducing automation into any process and the problem of finding the people to plan automation systems. The second lecture, dealing with the social consequences of automation, considers the need for anticipating its effects and the character of the new society in which automation is widely used. Besides the planning for this future, there is the problem of ensuring that the plan is feasible and also the further problem of providing the type of labour required. Finally, Mr. Thompson stresses the need to educate people to fit them for such a future and the importance of minimizing the effects of change. He suggests that a new emphasis should be placed on the real purpose of economic change; we must ensure that automation is made to serve our deepest needs, to give more leisure and to make work more interesting, so that we find greater contentment and happiness.

Research in Human Genetics and Studies of Twins

THE World Health Organization, in recognition of the increasingly important part that genetic studies are playing in the medical sciences, has established at its headquarters in Geneva a Human Genetics Unit. The purpose of the Unit is to co-ordinate and stimulate research and training in human genetics. Dr. R. L. Kirk, who is in charge of the new Unit, was formerly reader in human genetics in the University of Western Australia, where his research was concerned mainly with population genetic studies in isolated groups in south and south-east Asia, Australia and the Western Pacific. Current activities of the new Unit in Geneva include investigations of populations of unusual genetic interest, study of various hereditary conditions such as haemoglobinopathies, the setting up of facilities to service research projects, such as international reference centres for genetic markers, and improvement and standardization of methodology in genetic studies. The Unit hopes to give increasing attention to research on the distribution and public health significance of the haemoglobinopathies, including the thalassaemias and glucose-6-phosphate dehydrogenase deficiency, as well as to stimulate interest in new methods of treatment for cases of homozygous sickle-cell disease and thalassaemia.

The use of twins in epidemiological and genetic research is being evaluated at the present time, and the World Health Organization hopes to act in future as a clearing-house for information on twin studies. It also hopes to play an important part in co-ordinating population genetic studies, particularly those concerned with populations still having a food-gathering or simple agricultural economy, or living as isolates in more highly developed communities. Future activities will be directed toward

the role of genetic factors in mental disorder, the standardization of techniques in studying chromosome aberrations associated with spontaneous abortion, the study of somatic cell genetics and the genetic consequences of exposure to novel chemicals in the human environment.

Portraits of Tasmanian Aborigines

ALTHOUGH the aborigines of Tasmania have been extinct for some decades, a number of portraits of them are in existence which are of considerable anthropological interest. An account of them, the circumstances which they were produced and passed into the hands of various collectors, together with their present whereabouts, has recently been published (*Records of the Queen Victoria Museum, Launceston. New Series, No. 1. Thomas Bock's Portraits of the Tasmanian Aborigines* By N. J. B. Plomley. Pp. 24 (10 plates). Launceston: The Queen Victoria Museum, 1965.) The portraits are in water-colour. The originals are almost certainly the work of Thomas Bock, an engraver who was transported to Tasmania in 1824, and they were made at the request of G. A. Robinson, who was engaged on expeditions of conciliation with the aborigines at that time. Duplicates were also produced by Bock as well as by his son, Alfred Bock, along with other artists, mainly for Lady Franklin, wife of the Governor General. Later, many of the pictures found their way into the hands of collectors, like Dr. Joseph Barnard Davis, a surgeon living at Shelton, Staffordshire, and Richard Cull, who was secretary of the then Ethnological Society. Now, most of the portraits form part of permanent collections at the Pitt-Rivers Museum, Oxford, the British Museum, the Royal Anthropological Institute, the Fuller Collection (London), the Tasmanian Museum, and the Queen Victoria Museum, Launceston, Tasmania. Some of them were housed in the Crystal Palace, and were destroyed by the fire in 1936. The paper contains twenty reproductions of the portraits in black-and-white. On aesthetic grounds alone they are of outstanding merit; and while it is now impossible to judge of their quality as likenesses, they are impressively life-like, constituting a record of the characteristics and facial expressions of a group of people which is compelling and unique.

The Great Barrier Reef, Australia

THE Editor has received the following communication from Dr. O. A. Jones, chairman of the Great Barrier Reef Committee, Australia: "I would like to draw the attention of your readers to the greatly expanded facilities for research on the Great Barrier Reef, Australia. The Great Barrier Reef Committee has recently spent nearly £30,000 on providing living accommodation and additional laboratory space and equipment. The facilities might be described as rather more than basic, in that they include, in addition to collecting gear and preserving materials, such items as a fume cupboard, microscopes, centrifuge, mettler balances and an incubator. There is fresh and salt water on tap, gas for laboratory heating and cooking, refrigeration (both laboratory and domestic), electric light and power, aquaria and two small boats. Scientists from anywhere in the world may live in reasonable comfort at the Station and carry out research programmes, short or lengthy, of their own choice in any of the scientific disciplines applicable to barrier reefs. The Station is admirably situated for carrying out sedimentation and beach rock studies as well as marine biology. Heron Island Reef is about twelve square miles in area; neighbouring Wistari Reef is much larger, and there are nineteen other reefs within an area of forty square miles. The fauna of Heron and Wistari Reefs is protected by law, but scientists may collect specimens for their research under Government permits. Additional information is obtainable from the honorary secretary, Dr. R. Endean, Department of Zoology, University of Queensland, Brisbane, Australia."

International Conference on Mechanisms and Machines

DURING September 27–October 1 the first international inference to be held in Bulgaria took place at Drouzhba sort, near to Varna. Delegates from Canada, the United Kingdom, Australia, Czechoslovakia, both German Republics, Hungary, Italy, Poland and the U.S.S.R. were present, and the topics under discussion ranged from the termination of the instantaneous screw axes in spatial mechanisms, and from non-linear problems of centrifugal endulum vibration absorbers to the design of electronic computers and of high-speed input–output devices. The levels of presentation and of technical content of all the papers were high; thus, together with the excellent organization of the conference, and the really beautiful situation of the hall—not 20 yards from a sandy beach and the Black Sea—made the event one which will be long remembered with pleasure by those who were present. An important outcome of the meeting has been the setting up of an informal communications system for the interchange of information in a field which is of interest and importance—but as yet not provided with a recognized journal.

'Clean Room' Technology

A CONFERENCE was held at the Technische Hochschule, Stuttgart, during September 6–7, under the chairmanship of Dr. R. Kratel. About a hundred scientists and engineers attended, most of the main German firms engaged in ventilation and air filtration being represented. A message was received from the American Association for Contamination Control. The first day was devoted to the physics of aerosols. Dr. C. N. Davies gave a general account of the deposition of airborne contamination by diffusion processes and by mechanical effects from air at rest and in laminar and turbulent flow. Natural aerosols in the atmosphere were described by Dr. K. Bullrich of Mainz University. Two papers followed on the analysis of aerosols, Dr. Gahm, of Zeiss, giving a complete analysis of limiting factors in visual microscopy, and Prof. R. Hodgkinson, of Virginia State College, discussing the performance of automatic optical dust counting instruments in the light of the Mie theory of light-scattering and recent research on the effect of varying design factors, such as angle of acceptance. During the second day, problems of immediate practical application were dealt with. Dr. D. Hasenclever, of Staubforschungsinstitut, Bonn, gave an analysis of filter performance, and J. R. Weersing, of Royco Instruments, dealt with recent findings on the performance of his firm's particle counter which was developed particularly for use in factories making components for missiles in the United States. The need for dust-free work-places is strongly felt in the electronics industry, and some typical problems in International Business Machines Corp. were explained by Dr. Lechler. The conference concluded with an address by Dr. Kratel, who considered the correct lines for industrial development and the question of standards of aerosol concentration and particle size.

American Society of Plant Physiologists : Awards

PROF. FRITS W. WENT, of the University of Nevada, has been awarded the Charles Reid Barnes Life Membership Award of the American Society of Plant Physiologists. Each year the Society confers this distinction on a senior member of the profession in recognition of his character and contributions to scientific research. Prof. Went is recognized for his broad contributions to the field of botany and for his pioneering research on the bioassay of plant hormones (auxins). His work laid the foundation for the agricultural success of synthetic weed killers, fruit drop inhibitors, and the many other practical applications of these substances. Prof. Went was also concerned with pioneering research in the quantitative study of the effect of weather on plants. This culminated in his

development of the air-conditioned greenhouse (phyton) which has led to the plant growth chambers that are now part of the equipment of every major botanical laboratory. His manifold other interests include investigations of the formation of atmospheric smog from plant volatile exudates, the interrelationships of various plant species with each other, the discovery of many of the properties of plant hormones, and the physiology of desert plants. In addition to his scientific research, Prof. Went has achieved recognition through his effective lecturing, inspiring teaching and competent administration, which have been recognized through professorships at the California Institute of Technology, and the Washington University, St. Louis, and the directorship of the Missouri Botanical Garden.

Officers

The following have been elected officers of the American Society of Plant Physiologists: *President*, Prof. A. Carl Leopold (Purdue University); *Vice-President*, Prof. Robert S. Bandurski (Michigan State University); *Secretary*, Prof. Robert S. Loomis (University of California at Davis). Prof. Kenneth V. Thimann, of the University of California at Santa Cruz, has been elected to the Executive Committee.

University News:

Birmingham

THE following appointments have been made: *Lecturers*, Dr. A. J. Biddlstone (chemical engineering); Dr. I. L. Dillamore (physical metallurgy); D. E. Evans (physics); Dr. A. W. Nicol (mining and minerals engineering); Dr. N. M. Queen (mathematical physics); Dr. K. H. Star (psychology); *Senior Research Fellow*, Dr. J. Stephen (microbiology); *Research Fellows*, B. E. P. Beeston, M. D. Hunt, M. Norman and R. J. M. Willcox (physical metallurgy); Dr. M. Cordey-Hayes (physics); Dr. R. Haque (mining and minerals engineering); M. A. S. Sweet (electronic and electrical engineering); D. R. Whitehouse (chemistry); R. C. Woodman (engineering production); Dr. A. J. Collings (medical biochemistry and pharmacology).

Announcements

DR. SIGVARD EKLUND (Sweden), director general of the International Atomic Energy Agency since December 1, 1961, was reappointed for a second four-year term of office at the Agency's General Conference in Tokyo on September 27.

A SYMPOSIUM on "Subcellular Movement", arranged by the American Society for Cell Biology, will be held in Philadelphia during November 10–12. Further information can be obtained from Professional Associates, 6520 Clayton Road, St. Louis, Missouri.

AN international symposium on "Volcanology", sponsored by the International Association of Volcanology of the International Union of Geodesy and Geophysics and organized by the New Zealand Geological Survey, will be held in Rotorua and Wellington, Auckland, during November 22–December 3. The two particular subjects proposed for the symposium are: rhyolites, ignimbrites and pumice, and associated volcanism; geothermal resources with particular reference to the origin, geology, geophysics and geochemistry of hydrothermal systems of possible economic importance. Further information can be obtained from the Secretary, International Symposium on Volcanology, P.O. Box 499, Rotorua.

ERRATUM. In the article entitled "Light-induced Stomatal Opening and the Postulated Role of Glycolic Acid", by Prof. O. V. S. Heath, Dr. T. A. Mansfield and Dr. Hans Meidner, which appeared on p. 960 of the August 28 issue of *Nature*, in column 1 line 13 from bottom on p. 961 '1.34' should read '1.34' (that is, a lower log stomatal resistance in blue than in red light).

THE INSTITUTE OF PHYSICS AND THE PHYSICAL SOCIETY

THE fifth annual report of the Council of the Institute of Physics and the Physical Society* covers the period ending on December 31, 1964, and incorporates details of the activities of the various committees, branches and groups of the Institute and Society, together with the financial statement and account for the year. The report was presented and adopted at the annual general meeting held on July 6, 1965, at the headquarters of the Institute and Society, 47 Belgrave Square, London.

During the year under review, 970 applications for election or transfer to the various grades of membership were received, compared with 1,165 in 1963. The total membership of 9,750 on December 31, 1964, consisted of 1,416 Fellows, 3,558 associates and 2,444 graduates of the Institute and 1,256 Fellows of the Physical Society, in addition to students and subscribers. Although this represents a net increase of 280, the rate of growth has declined during the past two years, and the Council in its report expresses considerable concern. It is known that many physicists qualified to become members attend the scientific meetings and conferences organized by the Institute and Society, but nevertheless do not apply for membership. Various methods to improve recruitment are under active consideration by the Membership and Education Committee. A new grade of membership, Licentiate, intended for assistants in laboratories possessing a knowledge of physics not quite so extensive as that required for graduateship, and for certain teachers in schools and technical colleges, became operative at the beginning of 1965.

Representatives of the Institute and Society visited five technical colleges, and the applications of three of these colleges for recognition or extension of recognition for the purpose of the membership regulations were approved. Sixty-two technical colleges presented 892 candidates for the Ordinary National and forty-one colleges 614 candidates for the Higher National Certificate in applied physics; 589 and 418 respectively were successful. Examinations for the Higher National Diploma in applied physics were held for the first time during 1964. Twelve of the thirteen candidates entered by two colleges were successful. The seven question papers set in Part 2, and the four compulsory papers and the general paper in Part 1 of the graduateship examination were published in the October issue of the *Bulletin* of the Institute and Society, and also as a separate booklet. Of the 97 candidates for Part 2, 27 passed (two with honours), and of the 79 for Part 1, only 12 were successful.

An enquiry conducted by the Membership and Education Committee revealed that 1,597 students were admitted at the beginning of the session 1964-65 to the 1,907 available places in the physics departments of the universities (excluding the University of Cambridge) in England and Wales. The corresponding figures for 1963 were 1,524 and 1,708 respectively. A report on the survey of salaries and emoluments received by the members of the Institute as at August 1, 1964, was published in the January 1965 issue of the *Bulletin*. This was the sixth survey carried out by the Institute and the first since the amalgamation of the Institute and the Society. A sub-committee of the Membership and Education Committee is now completing a revision of the first draft of a statement on professional conduct which deals mainly with terms and conditions of employment and consulting work. The revised draft is to be printed and submitted to members for comment and revision before adoption.

The Institute and Society were responsible for the organization of the international conference on magnetism held during September 7-11, 1964, at the University of Nottingham. More than 500 attended the conference and

some 230 papers were presented. The text of the 19 Guthrie Lecture, on the subject of magnetic processes weak and moderate fields, which was delivered by Prof. L. F. Bates on September 9 during the conference, has now been published (*Proc. Phys. Soc.*, 84, 625; Nov 1964). The lecture had been specially postponed so that Prof. Bates might deliver it in his own Department Nottingham. Many other conferences and symposia were organized and held during 1964, both by the Meeting Committee and the Nuclear Physics and Solid-state Physics Sub-committees of the Institute and Society and by the twelve branches and eleven specialist subject groups. Details of these are given in the annual report.

The 1964 Guthrie Lecture, which was delivered by Prof. M. Ryle on October 1 during the autumn conference of the Electronics Group at the University of Keele, was entitled "Radio Telescopes" and the text appears in the February 1965 issue of the *Proceedings of the Physical Society* (85, 201; 1965). Dr. P. H. Fowler, who gave the 1964 Rutherford Memorial Lecture on September 9 during the conference on "Low- and Medium-energy Nuclear Physics" at the University of Sussex, spoke on the subject of "Pi-mesons versus Cancer" (*Proc. Phys. Soc.*, 85, 1051 June 1965). Dr. A. R. Lang received the Charles Vernon Boys Prize for his development of the technique of X-ray topography, and Dr. W. Marshall the Maxwell Medal and Prize for his contributions to the theory of magnetism. The presentations were made at the annual dinner of the Institute and Society in London on May 5, 1964. Prof. J. Friedel was awarded the 1964 Holweck Medal and Prize for his work on the electronic structure of metals. The Council has decided that after 1965 the Guthrie and Rutherford Lectures will be replaced by the awards of medals and prizes.

The forty-eighth annual exhibition of scientific instruments and apparatus was held during January 6-9, 1964 in the two halls of the Royal Horticultural Society, London. The *Journal of Scientific Instruments*, in its May 1964 issue, contained several articles and a special survey devoted to equipment displayed at the exhibition. The careful selection of exhibits and the section devoted to educational instruments and experiments were commendable features. The *British Journal of Applied Physics* revised its format to that of the *Proceedings*, but retained the original colour of its cover. A reorganization of subject-matter between the two journals was made. The volume of material submitted to the Institute and Society's three journals continues to increase, but the report directs attention to the growing number of papers which in the form received are unacceptable for publication. The Council had decided to launch a new monthly journal, the *Journal of Physics Education*, principally for sixth-form teachers of physics. In co-operation with other scientific bodies the Institute and Society have urged that closer collaboration be established between editors of physics journals so that by better choice and improvement of articles and by uniformity of presentation the standing and sales of British journals may be enhanced. The *Student Monograph Series* of books, commenced in 1953 and intended for students of the Higher National Certificate in applied physics, has since been widened in scope for undergraduate and graduate students, but since there are now adequate publications of this kind it has been decided to complete the series with the publication of "Subjective Limitations on Physical Measurements" by C. A. Padgham. The volume entitled "Dimensional Analysis and Scale Factors", by R. C. Pankhurst, was published during 1964.

The financial statement refers to the gratifying increase of £13,964 in members' fees and to the increases in the exhibition receipts and in non-members' conference fees. The increase in activities and the general rise in costs

* Report of the Council of the Institute of Physics and the Physical Society for the year 1964. Pp. 25. (London: The Institute of Physics and the Physical Society, 1965.)

combined to raise the total expenditure, and the total surpluses at the end of the year of £158,673 still fell short of the aim to obtain a sum equal to the amount required for one year's working.

The report gives prominence to the proposal by the Council in July 1964, and the agreement in December 1964, to purchase the Fulmer Research Institute. The reasons for the bold venture were announced in the February issue of the *Bulletin* when the purchase was made. Not only will the staff at the Research Institute benefit from the association with the Institute and Society, but investment by the Institute and Society in sponsored

research, regarded solely as a business venture, will be evidence that the Council is of the opinion that the application of physics to industry is a paying proposition. The purchase was made possible by the generous terms of the owners' offer and by a substantial interest-free loan made to the Institute and Society by Imperial Chemical Industries, Ltd. It is intended that surplus revenue from the Fulmer Institute will be used to help to replace the income at present derived from the seven-year covenants signed by a number of industrial firms in favour of the Physics Trust Fund and which will stop in 1967 and 1968.

S. WEINTROUB

SCIENTIFIC RESEARCH IN NEW ZEALAND

THE National Research Advisory Council, New Zealand, was established by the National Research Advisory Council Act of 1963 to advise the Minister of Science on matters related to scientific research in New Zealand. Its first annual report covers the year ending March 31, 1965*.

At its first meeting in April 1964, the National Research Advisory Council decided to set up 16 working parties to review and report on research and service in various fields. The reports of these working parties cover: (1) *agriculture and forestry*, the dairy industry, field crops, forestry, horticulture, meat and wool; (2) *secondary and tertiary industry*, building and construction, manufacturing and engineering, and transport; (3) *earth and related sciences*, the atmospheric sciences, mineral resources, oceanography, limnology and fisheries and solid earth sciences; (4) *basic sciences*, training and services, atomic energy (scientific services for Government departments and agencies are appended); (5) *manpower, education and training* (this report was deliberately delayed until the working party was able to consider the recommendations of the other working parties and to obtain additional information on manpower).

Meanwhile, the Council is satisfied that the implementation of its present recommendations is feasible and would not be jeopardized by a shortage of trained manpower.

For the year ended March 31, 1965, the estimated expenditure on scientific research and services was about £7.5 million and in addition £827,000 was scheduled for expenditure on new laboratories for Government departments and research associations; the total expenditure represented about 0.48 per cent of the gross national product. Of the £7.5 millions, £6.1 millions was provided in the votes of eleven Government departments and, of this, £661,000 went in grants to other research organizations. These figures probably underestimate the total expenditure on science since no allowance is made for expansion by the Post Office, railways, the Broadcasting Corporation, or for the salaries of university staff, accom-

modation or services provided from university funds and used in part for research.

Between 1954-55 and 1964-65 expenditure on science in New Zealand increased from £2.73 millions at about 10 per cent annually, and the scientific staff in Government departments increased in the same period from 568 to about 800. The Council suggests that investment in research for an industry should depend on such criteria as the annual value of production; the national importance of the industry; the significance and number of problems affecting the industry; the chances of a solution being found to selected problems, taking into account the amount of existing scientific information required; the calibre of the staff available and the availability of suitable facilities; the application of results, bearing in mind the problem of implementation because of difficulties of liaison and information services and the time-lag in the application of research results.

The Council recommends that every effort should be made to increase the research effort directed towards New Zealand's agricultural and pastoral products, particularly those of the meat, wool and dairy industries, and that over the next five years research expenditure in this area should be increased cumulatively by £320,000 a year. Forestry research also requires expansion, and a cumulative increase in expenditure of £40,000 per year is recommended. Very high priority to research into problems of the transport industry is also recommended, including an expenditure starting at £10,000 a year and rising to £50,000 a year in five years, while a Transport Research Advisory Committee should be set up to advise the Commissioner of Transport on the operations of the proposed Research Unit. An additional £26,000 is recommended for the existing building research units, and increased support for operational research in the Department of Scientific and Industrial Research and other organizations is highly desirable. An increase in the next year of about £3,000, rising to £18,000 in about five years, is suggested, and £50,000 should be granted for implementing the second year's recommendations of the report of the Mineral Resources Committee.

COMPARATIVE STUDY OF HOUSING IN BRITAIN, FRANCE AND WESTERN GERMANY

BROADSHEET No. 490, issued by Political and Economic Planning and prepared by E. G. Howes, deals with housing in Britain, France and Western Germany*.

In Britain, building research is financed to the extent of about £900,000 per annum at the Building Research

Station, and some £100,000 is spent by the Civil Engineering Research Council; the Minister of Works and Public Building has placed research contracts to the amount of £50,000 with universities. Most building research is carried out privately, but whether this is adequate and whether the information gained is accessible is regarded as very doubtful. In Germany the Federal Government and the Regents devote considerable funds to research and the nationalization of techniques and procedure, and also

* *Planning*, 31, No. 490 (August 1965): *Housing in Britain, France, and Western Germany*. By Eric G. Howes. Pp. 215-270. (London: Political and Economic Planning, 1965.) 7s 6d.

support exhibitions, publications, films and other means of disseminating information (no figures for expenditure, however, are given in the Broadsheet).

For the rest, the Broadsheet concludes that British standards in housing are still high in comparison with those of France, but are being overtaken by those of West Germany. In numbers of dwellings built in recent years (until 1964) Britain has been lagging. Her present need is to step up new building schedules, particularly of dwellings to let, and to demolish and replace slums. Housing policy in Britain has been confused by indecision as to whether the provision of houses should be regarded as a social service, or as a commercial operation. The existence of subsidized and also non-profit housing has almost completely stopped the investment of private capital in dwellings for letting.

While it is proper that local authorities should have the major responsibilities for housing families of all income-levels, it may be argued that subsidies should be reserved for those families that, because of age, lack of earning capacity, or other handicaps, are unable to afford economic rents. In both France and Western Germany the policy is to grant housing allowances to such families and the consequences of adopting such a system in Britain should be explored. In Britain the National Assistance Board pays out rent allowances to 1.5 million families that are eligible for assistance, but the policy elsewhere is to make a clear distinction between housing allowances and public assistance. It is desirable also to diversify the means by which houses for letting at economic rents should be provided: the recently created Housing Corporation should be given every support in its encouragement of cost-rent and ownership societies. There seems to be no point in deterring the private sector from competing in this field.

Adoption of long-term planning policies would enable those engaged in producing dwellings to plan ahead and to

concentrate on their work without fear of too frequent change. It is impossible to ignore the success of German housing problem and the extent to which that attributable to long-term policies. The efforts of West Germany to influence the supply and price of building land have not always been fully rewarded, but have achieved some part of their object. Ways and means whereby the British Government could exert an adequate influence have received intensive study, and action now urgently required. If tax concessions are to be given to some form of saving, like those of Trustee Savings Banks, it is arguable that equivalent concessions should be awarded to Building Societies, the efforts of which directed exclusively to providing finance for housing. The psychological and material effects of such measures have been clearly demonstrated in Western Germany by the successful revival of the saving habit. Encouragement should be given to the house-building part of construction industry to rationalize its organization, to out restrictive practices, intensify training and make the best possible use of the skills and knowledge of its management and work people. The possibility of further curtailment of the apprenticeship period with more intensive training and training on actual work is worth considering. Consideration might also be given to whether it is possible to allow public, commercial and industrial building to outstrip the building of dwellings. Experience in Germany and France suggests that self-building societies, which in small way have done useful work, could be more vigorously encouraged in Britain.

The Broadsheet considers that the trained personnel of the British building industry are probably of as high calibre as, if not higher than, their counterpart in other countries, and to perform the task that confronts them they need only the leadership, guidance and encouragement that vigorous Government backing can provide.

INSPECTION OF ALKALI, ETC., WORKS

THE one hundred and first annual report on alkali, etc., works in England and Wales, prepared by the Chief Inspector*, covers the year 1964. It stresses the co-operation of industry with the Inspectorate without which, individually by works, and collectively through research associations, and the like, the task of the Inspectorate would be much more onerous. Certainly without this co-operation the Inspectorate would have to be multiplied several times in size and a department would be needed for specialized techniques of waste gas sampling and analysis, as well as for developing control measures for air pollution. The number of works registered under the Act at the end of the year was 1,995, involving the operation of 3,208 processes, and 11,966 visits and inspections were paid during the year, compared with 10,850 in 1963, including 123 special visits by the Chief and Deputy Chief Inspectors. Of this total, 231 were to, or in connexion with, works not registered under the Act, 46 were concerned with control of radioactive emissions and 37 were to, or in connexion with, colliery spoilbanks. During the inspections 4,563 quantitative analyses were made of gases evolved from processes in operation, compared with 3,433 in 1963, while 746 special samples, compared with 615 in 1963, were taken and submitted to the Government Chemist.

The report also emphasizes the effect of the changing face of industry on the task and responsibilities of the inspectorate; a searching and realistic appraisal of the responsibilities and day-to-day activities of the inspectorate has been made. A historical and technical review of the decline and fall of the traditional sulphuric acid

lead chamber process and one of the early days of the copper industry are included.

In the belief that most new contact sulphuric acid plants will burn sulphur of high quality as the raw material, tables have been prepared giving the stack heights for final discharge of waste gases from units in clusters of units making daily 200–2,000 tons of monohydrate. If different raw materials are used it will be a simple matter for inspectors and industry to calculate appropriate chimney heights using the information given and to apply it to the particular permitted loss of sulphur burned. Reference is again made to mist emission from certain contact sulphuric acid plants, and while our knowledge of the reasons for this is still obscure the problem receives the close attention of the Inspectorate (some progress appears to have been made).

The Chief Inspector, under "Alkali, etc., Works and Regulations (Scotland) Acts, 1906 and 1951", records that at December 31, 1964, 263 works were registered under the 1906 Act, and 361 processes were inspected within these works. 622 visits were paid by the Inspectorate on works under the Act or in the interest of preventing air pollution, of which 420 were to premises registered under the Act of 1906.

Further experimental testing of emissions of dust from registered premises was carried out on behalf of the Inspectorate by the two-man team provided on contract by the Department of Scientific and Industrial Research. Thirteen works were covered in 41 visits, and 87 tests were made mostly at the electricity power stations. In general, inspections showed that the provisions of the Act were observed in good spirit as well as with attention to the tests.

INTERACTION OF CEPHALORIDINE WITH PENICILLINASE-PRODUCING GRAM-NEGATIVE BACTERIA

By DR. J. M. T. HAMILTON-MILLER, DR J. T. SMITH and PROF. R. KNOX

Department of Bacteriology, Guy's Hospital Medical School, London

CEPHALORIDINE (7-((2-thienyl) acetamido)-3-(1-pyridylmethyl) cephalosporanic acid, 'Ceporin') has been shown to be of value in the treatment of infections caused by Gram-negative bacteria^{2,3}. Although many cephalosporins are resistant to hydrolysis by β -lactamases in Gram-positive bacteria^{1,2,4,5}, there have been several reports^{2,6-10} that they are readily hydrolysed by certain Gram-negative bacteria. This destruction has been attributed to an enzyme 'cephalosporinase', although it has seldom been shown to be enzymatic and the end-product has not been identified. In view of these reports, it was decided to investigate the action of organisms known to produce penicillinase (EC 3.5.2.6.) on cephaloridine, and the action of cephaloridine on these strains of bacteria. In addition, the relationship between 'cephalosporinase' and 'penicillinase' activities was studied. The following bacterial strains were used in the investigations: *Klebsiella aerogenes* 1, 43, 83, 366, 370, 373, 2, 407, 414, 415 and 418; *K. ozaenae* 61; *Escherichia coli* 214T, 419, K 12 (F⁻ met⁻) and TEM; *Aerobacter aerogenes* 15 and 53. All these strains produce penicillinase constitutively. *Proteus morgani* G and 185 and *Pr. tegeri* 410, which produce an inducible penicillinase, were also used. We are very grateful to Dr. Naomi Datta for supplying *E. coli* K 12 and TEM. All the other strains were isolated from clinical specimens at Guy's Hospital and are referred to by their laboratory reference numbers. Organisms were cultured in infusion broth, collected by centrifugation and disrupted by ultrasonic treatment, previously described^{11,12}. The *Proteus* strains, which gave little or no basal penicillinase activity¹³, were cultured in sub-inhibitory concentrations of benzylpenicillin, inducing agent before gathering. Such cell-free penicillinase preparations hydrolysed the β -lactam bond in certain penicillins, and it was of interest to determine whether the β -lactam bond present in cephaloridine was so susceptible to hydrolysis by these β -lactamases. The rates of destruction of penicillins and of cephaloridine, brought about by the β -lactamase preparations, were measured either acidimetrically (by the spectrophotometric method), or by the hydroxylamine method. This latter method had to be modified slightly from that previously used¹²: it was found that the hydroxamate of cephaloridine was somewhat unstable, in that it started to decompose after about 5 min; however, the hydroxamate was fully formed in 3 min, and addition of the ferric ammonium sulphate reagent at this time gave a chromogen of maximum intensity. With this modification, satisfactory results were obtained by the use of this assay both for cephaloridine and for penicillins.

Rate of hydrolysis of cephaloridine. Cell-free penicillinase preparations from the various strains were incubated in the presence of cephaloridine (initial concentration 5 mM) at 37° in 25 mM sodium phosphate buffer, pH 7.4; the rate at which cephaloridine was destroyed by each preparation was compared with the rates of hydrolysis of benzylpenicillin, ampicillin and 6-aminopenicillanic acid. Results are shown in Table 1, taking the rate of benzylpenicillin hydrolysis as 100 in each case. It can be seen that cell-free extracts of the *Klebsiella* and *Aerobacter* strains destroy cephaloridine at approximately the same rate as 6-aminopenicillanic acid, but less rapidly than ampicillin; the *E. coli* and *Proteus* preparations, however, which destroy ampicillin and 6-aminopenicillanic acid only very slowly, hydrolyse cephaloridine more rapidly than benzylpenicillin under these conditions.

The enzymes from the *Proteus* strains hydrolyse cephaloridine many times more rapidly than benzylpenicillin.

Identity of 'penicillinase' with 'cephalosporinase'. The distinction between penicillinase and cephalosporinase activity is not at all clear. Some authors^{4,10} claim that cephalosporinases and penicillinases are different enzymes whereas Ayliffe⁶ leaves the question open. The following three approaches were used in an attempt to answer this question.

(1) Cell-free extracts of *A. cloacae* 53, *E. coli* 214T and 419 and *K. aerogenes* 366 were treated with protamine sulphate to remove nucleoprotein, and the supernatant fractions were gel filtered on 'Sephadex G50'; each fraction was then assayed against both benzylpenicillin and cephaloridine. In each case, destruction of the two substrates ran in parallel in each fraction.

(2) Penicillinase preparations from *K. aerogenes* 366 and 373 were exposed to 1.31 mM iodine in 2 mM potassium iodide for 1, 2 or 3 min, at 30°, the reaction being stopped when required by the addition of an appropriate volume of 19 mM sodium thiosulphate. Aliquots were then assayed in parallel against benzylpenicillin and against cephaloridine. In each instance, reduction of the 'penicillinase' activity occurred to precisely the same extent as did reduction of the 'cephalosporinase' activity.

(3) The three *Proteus* strains were cultured in the presence of a range of concentrations of benzylpenicillin, varying from one-half to one-twentieth of the minimum inhibitory concentration. Cell-free preparations were then assayed against benzylpenicillin and against cephaloridine. In the absence of inducing agent, there was no activity against either substrate, but in cultures grown in the presence of benzylpenicillin, induction of 'penicillinase' activity ran quantitatively parallel to induction of 'cephalosporinase' activity, for each concentration of inducing agent.

Thus these data suggest that, in the strains investigated so far, penicillinase and cephalosporinase activities are manifestations of one and the same enzyme.

Affinity of substrates for enzymes. The effect on the rate of hydrolysis of varying the concentration of various

Table 1. RATES OF HYDROLYSIS OF CEPHALORIDINE, AMPICILLIN AND 6-AMINOPENICILLANIC ACID BY CELL-FREE PREPARATIONS OF PENICILLINASE-PRODUCING GRAM-NEGATIVE BACTERIA IN M/40 SODIUM PHOSPHATE BUFFER pH 7.4

Initial substrate concentration was 5 mM. The rate of destruction of benzylpenicillin is expressed in μ moles/min/10⁹ bacteria/ml. The rates of destruction for the other β -lactam antibiotics are expressed in terms of μ moles/min, taking the rate of destruction of benzylpenicillin as 100 in each case

—, Destruction too slow to be measured accurately (that is, < 10).

substrates was investigated, using cell-free bacterial extracts, by the use of the spectrophotometric assay. From the progress curves obtained, Michaelis constants were calculated where possible; results are shown in Table 2. Cephaloridine has a lower affinity, as can be seen, for the penicillinases from the *K. aerogenes* and *E. coli* strains than have either benzylpenicillin or ampicillin; thus, at concentrations that are obtained in the blood¹ during therapy (approximately 20 μ M), cephaloridine will be at least 17 times as stable as ampicillin to *K. aerogenes* penicillinase. In the case of the *A. cloacae* enzyme, the affinity of cephaloridine is some 8 times as high as that of ampicillin. Thus, by calculation, towards the penicillinase of this organism cephaloridine will be 3.5 times as labile as ampicillin, at concentrations attained therapeutically; this should be contrasted with the situation at 5 mM (Table 1), when cephaloridine is less labile than ampicillin.

Ease of entry into intact bacteria. Most penicillinase-producing Gram-negative bacteria studied in this laboratory¹¹ possess accessibility barriers against penicillins; the extent of the barrier for any one substrate is expressed as the 'permeability factor'¹⁴ (which is the fold increase in hydrolytic activity toward a substrate subsequent to disruption of an intact bacterial suspension). Permeability factors have been determined for benzylpenicillin, ampicillin, 6-aminopenicillanic acid and cephaloridine for 18 strains; values are tabulated in Table 3. The *Proteus* strains have been omitted because the extent of the permeability barrier depends on the nature and the concentration of the inducing agent¹³. From the results it is quite clear that cephaloridine can enter bacterial cells of every strain tested with complete freedom, whereas these same cells possess a marked accessibility barrier to benzylpenicillin and ampicillin. 6-aminopenicillanic acid, although obtaining considerably easier access than the latter two compounds, does not have complete freedom of entry in all strains. A consequence of this free access is that, whereas the crude penicillinase of *A. cloacae* 53 hydrolyses cephaloridine at 61 per cent of the rate of ampicillin (to which the intact cells have a permeability factor of 8), cephaloridine was found to be hydrolysed by intact cells about 5 times as rapidly as ampicillin. There does not seem to be an adequate explanation, in terms of molecular size, charge or the like, for this property of cephaloridine. One explanation which could be put forward to account for this phenomenon is that cephaloridine affects the cells so that the penicillinase becomes extracellular and thus there is no longer any barrier between enzyme and substrate. However, this was disproved by the findings in the following experiment.

Table 2. AFFINITY OF CELL-FREE PENICILLINASE PREPARATIONS FOR THREE SUBSTRATES

Whole-cell suspensions were assayed against cephaloridine (initial concentration 5 mM); they were then spun down, re-suspended in fresh buffer and re-assayed against cephaloridine. It was found, allowing for small losses due to lysis and the centrifugation and re-suspending operations, that the pre-incubation with cephaloridine had no resulted in any loss of enzyme from the intact cells in the supernatant fluid.

Inhibition of penicillinase activity. The hydrolysis of benzylpenicillin by penicillinases from Gram-negative bacteria is inhibited by methicillin, certain isoxazol penicillins and quinacillin^{14,15}. I_{50} values¹⁶ were determined, using cephaloridine (2.7 mM) as substrate, for methicillin, cloxacillin and quinacillin; results are shown in Table 4 (the I_{50} values obtained previously^{14,15} using benzylpenicillin as substrate for *K. aerogenes* 366 and 373 enzymes are included for comparison); it is clear that cephaloridine hydrolysis by these penicillinases is more susceptible to inhibition than is benzylpenicillin hydrolysis. Inhibition of cephaloridine hydrolysis by methicillin appears to be competitive, as increasing the substrate concentration with a given amount of inhibitor decreases the amount of inhibition.

Antibacterial activity against penicillinase-producing Gram-negative bacteria. Minimum inhibitory concentrations were determined for cephaloridine, using the serial doubling dilution technique; two sizes of inoculum were used, about 10⁷ and 10 organisms per tube, and incubation was carried out for 16 h. Results are shown in Table 6. It can be seen that cephaloridine is approximately 10 times as effective as ampicillin against the penicillinase-producing ampicillin-resistant *K. aerogenes* strains against the other strains there seems to be little to choose between cephaloridine and ampicillin as regards antibacterial activity. In most cases there was a marked inoculum size effect¹⁶.

It is generally accepted that a direct causal relationship exists between penicillinase activity and resistance to hydrolysable penicillins. Cephaloridine was destroyed more rapidly than ampicillin by intact cells from the majority of the strains studied here and hence it would be expected that cephaloridine would be a less effective antibacterial agent than ampicillin. However, with the exception of the *Proteus* strains, the reverse was found to be true with the strains examined in this report. This apparently paradoxical situation can be explained by the discovery made here that the entry of cephaloridine into these Gram-negative bacteria is not hindered by a cellular

accessibility barrier, whereas entry of all the penicillins so hindered^{11,12}.

With eight strains of penicillinase-producing ampicillin-resistant *K. aerogenes* cephaloridine was found to be more effective than ampicillin, in terms of minimum inhibitory concentrations, against both large and small inocula. Even so, therapeutic administration of cephaloridine may not give rise to blood levels¹ sufficiently high to have an antibacterial action *in vivo* with these strains, but the levels attainable in urine¹ suggest that cephaloridine may have a place in the treatment of urinary tract infections caused by similar organisms. However, the *in vivo* performance of a drug cannot be predicted solely in terms of its effectiveness in *in vitro* sensitivity tests. Other factors, for example, absorption, excretion and possible allergism with penicillinase-resistant β -lactam antibiotics, must be considered before this antibiotic can be recommended for use in infections caused by penicillinase-producing Gram-negative bacteria.

We thank Beecham Research Laboratories, Ltd., Boots Pure Drug Co., Ltd., and Glaxo Laboratories for

gifts of penicillins and cephalosporins. We also thank Mrs. B. Heywood and Miss C. Nicholls for their assistance.

THE IRON DEXTRAN COMPLEX

By DR. C. R. RICKETTS

Medical Research Council Industrial Injuries and Burns Research Unit, Birmingham Accident Hospital

AND

DR J. S. G. COX, C. FITZMAURICE and G. F. MOSS

Research Department, Fisons Pharmaceuticals, Ltd., Holmes Chapel, Cheshire

PHARMACEUTICAL preparations ('Imferon' and 'Imposil', Fisons Pharmaceuticals, Ltd. (Benger Laboratories)) containing iron and dextran are used for the treatment of iron-deficiency anaemia in man and farm animals. They are prepared by neutralizing ferric chloride in the presence of an alkali-modified dextran and heating to form a stable clear brown solution. The nature of the linkage between the iron and the dextran and the molecular weight of the product are not known. The following techniques seemed likely to throw light on the nature of the iron dextran preparation: (1) gel-filtration on 'Sephadex'; (2) ultrafiltration; (3) separation in the ultracentrifuge in comparison with coloured proteins of known molecular weight.

Separation on 'Sephadex' columns. A column of 'Sephadex G200' (2.4 cm x 100 cm) using 0.9 per cent sodium chloride for elution was available and had previously been calibrated with dextran fractions of known molecular weight distribution (Pharmacia, Ltd.) and with serum proteins. The reproducibility of chromatography had been established using a sample of dextran labelled with iodine-125 (ref. 1); on successive runs the size of each fraction was reproducible within ± 1 per cent of the whole. In an initial experiment 'Imferon' (1 ml.) was mixed with 0.1 ml. of 0 per cent iodine-125 dextran and diluted to 5 ml. with saline. A sample of 1 ml. of this diluted solution was applied to the column and eluted with saline into 5-ml. fractions. Part of the iron was adsorbed on the 'Sephadex' making the whole column brown, the remaining iron being eluted. The adsorbed iron could not be eluted with saline and was finally recovered by elution with N sulphuric acid.

The radioactivity, the brown colour (430 m μ) of iron and the dextran con-

centration of the fractions are shown in Fig. 1. The radioactivity measurements showed that the chromatography was comparable with previous calibrations. From the position of the iron peak one might infer that the molecular weight of the iron dextran complex was less than that of the labelled dextran which had \bar{M}_w about 110,000. The peak lies between the positions of peaks previously found for dextrans of \bar{M}_w 75,000 and \bar{M}_w 40,000 and is closer to the lower value. The dextran peak is adjacent to the peak due to inorganic iodide ions and is to the low molecular weight side of a peak previously obtained with a dextran fraction of \bar{M}_w 9,400; its position is thus consistent with a molecular weight of about 5,000. However, the shape of this peak

Fig. 1. Gel-filtration of 'Imferon' on a column of 'Sephadex G200' in 0.9 per cent sodium chloride solution. The dotted line shows the distribution of radioactivity from ¹²⁵I dextran of \bar{M}_w 110,000 used as a reference substance. The dashed line and shaded area denote the distribution of iron and the solid line denotes the distribution of dextran from the 'Imferon'.

is worth considering. Dextrans of \bar{M}_w 40,000 and below give a symmetrical peak on columns of 'Sephadex G200'. Dextrans of higher molecular weight give an unsymmetrical peak, sharpened on the high molecular weight side, that is, the tail toward the low molecular weight side. The dextran peak in Fig. 1 has a tail toward the high molecular side, suggesting that the iron is carrying some of the dextran through the column ahead of most of the dextran. This is an indication of the existence of a linkage between the iron and the dextran existing under the physiological conditions of isotonic saline and a measured pH of 6.8. However, adding up the material in the fractions, 101 per cent of the radioactivity, 97.7 per cent of the dextran but only 32 per cent of the iron were recovered. Evidently 68 per cent of the iron had been separated from dextran under these mild conditions, possibly through competition for the iron between the dextran and 'Sephadex', which is a cross-linked and insoluble form of dextran.

This initial experiment suggested that 'Sephadex G75' might separate the iron-dextran complex from free dextran. Molar sodium sulphate solution was chosen in an attempt to minimize adsorption of iron on to 'Sephadex'.

A sample of 0.5 ml. of 1 in 5 dilution of 'Imferon' was applied to a column of 'Sephadex G75' (1.4 cm \times 48.5 cm) and eluted into 2 ml. fractions with M sodium sulphate. The separation of the iron complex from free dextran is shown in Fig. 2. Recovery of the iron was 87.4 per cent and of dextran was 95.5 per cent. Of the recovered dextran 61.4 per cent was free and the remainder was associated with iron. The iron-dextran ratio of fractions 9, 10 and 11 was 0.536, 0.533 and 0.470 respectively, that is, about two parts of dextran to one part of iron.

It was found that under the same conditions the dextran fraction used in the preparation of 'Imferon' was eluted in the same volume as the second dextran peak of Fig. 2. This would indicate that the second peak was either dextran liberated by breakdown of the complex, free dextran which was present in 'Imferon' but not complexed with iron or a combination of these.

Later experiments using a 'Sephadex G75' column showed that between 75-85 per cent of the iron could be recovered in the iron-dextran peak by elution with 0.9 per cent sodium chloride. These suggest that it may not have been an effect of ionic strength which was governing the adsorption of the iron on to 'Sephadex', but the length of time that the 'Imferon' was in contact

Fig. 2. Gel filtration of 'Imferon' on a column of 'Sephadex G75' in M sodium sulphate solution. The hatched area denotes the distribution of iron and the solid line denotes the distribution of dextran. —, Mg dextran in fraction; ---, mg iron in fraction

Fig. 3. The adsorption of iron on to 'Sephadex G75' in 0.9 per cent sodium chloride solution.

with the dextran gel. This was confirmed by examining the effect of flow-rate on the adsorption of iron on 'Sephadex G75' column. By elution at a flow-rate of 100 ml./h 70 per cent of the iron was recovered, whereas at 5 ml./h only 20 per cent of the iron was recovered.

There were no differences in the relative peak positions for the two fractionations but the amount of dextran associated with the iron in the first peak varied according to the flow-rate so that the iron to dextran ratio was 0.33 : 1 with a short elution time and 0.5 : 1 with a long elution time.

In order to examine further the effect of time on the adsorption of iron on to 'Sephadex' a 1-ml. aliquot of 1 in 20 dilution of 'Imferon' was added to 1 gm of 'Sephadex G75' in 50 ml. of 0.9 per cent sodium chloride. The mixture was shaken for 5 min and a 2-ml. aliquot removed, centrifuged and the iron content estimated on the clear supernatant using bathophenanthroline reagent². The mixture of 'Imferon' and 'Sephadex G75' was shaken for 24 h, 2-ml. samples being removed at intervals, centrifuged and the iron contents of the supernatants estimated. Fig. 3 shows the effect of plotting iron content of the supernatant against the time the 'Imferon' was in contact with 'Sephadex'. By 24 h, when an equilibrium appeared to have been established, 22 per cent of the added iron had been adsorbed by the 'Sephadex'. During the first 2-3 h there was a very rapid fall in the iron content of the supernatant while during the next 20 h the rate of adsorption of the iron was very much slower.

When the amount of added 'Imferon' was reduced to one-tenth of that in the previous experiment a similar result was obtained with 30 per cent of the iron being bound to the 'Sephadex'. Using a polyacrylamide gel in place of 'Sephadex' gave a similar result.

Ultrafiltration. The 'Sephadex' gel fractionation suggested that 'Imferon' might contain uncombined dextran and it was thought that this could be more easily separated using ultrafiltration.

'Imferon' was not retained by a membrane with a porosity of 10 μ , but cellulose ('Visking') film retained the iron-dextran complex while allowing uncombined dextran to pass through extremely slowly. In order to increase the pore size of the filter the membrane was treated with 60 per cent zinc chloride solution for 10 min. Membranes treated in such a way completely retained bovine haemoglobin, which has a diameter of 2.7 μ . A solution of 10 ml. of 'Imferon' diluted to 40 ml. with water was subjected to filtration through such a membrane at 80 lb./in.² pressure. At intervals the volume of the 'Imferon' solution was restored by adding quantities of water equal to the volume of fluid which had passed through the filter. After a period of three weeks a total of 160 ml. had filtered. Table 1 shows the analysis of the solutions.

Zone ultracentrifugation in a density gradient. Density gradient tubes were prepared³ containing carbon tetra-

Fig. 4. Ultracentrifugation, in a sucrose density gradient, of 'Imferon' and for comparison serum proteins coupled with 'Procion' dyes

loride (0.3 ml.), which has a density of 1.59, 30 per cent crose solution (2.3 ml.) of density 1.26 and 10 per cent crose (2.3 ml.) of density 1.07. The sample (0.2 ml.), having a density of less than 1.07, was carefully layered on top and the tubes were centrifuged at 35,000 r.p.m. for 16 h. Samples used were a 1 in 20 dilution of 'Imferon', a 4 per cent solution of albumin coupled with 'Procion' red dye (Imperial Chemical Industries, Ltd.) and a 4 per cent solution of γ -globulin coupled with 'Procion' blue dye (Imperial Chemical Industries, Ltd.). After centrifuging, the tubes presented the appearance shown in Fig. 4. Traces of insoluble protein had collected at the carbon tetrachloride interface. The iron colour was close and at the interface, indicating a much higher molecular weight than albumin 69,000 or γ -globulin 156,000.

Discussion

In the initial 'Sephadex' gel filtration experiment the position of the eluted iron peak lay between the positions previously found for dextrans of \bar{M}_w 75,000 and 40,000.

Table 1. ANALYSIS OF SOLUTIONS OBTAINED BY ULTRAFILTRATION OF 'IMFERON'

	Iron concentration	Dextran concentration	Iron dextran ratio
Original 'Imferon' solution	1.22%	5.42%	0.224
Final 'Imferon' solution	2.8%	6.7%	0.418
Ret 10 ml. filtrate	50 p.p.m.	2.3%	—
Ret 10 ml. filtrate	1 p.p.m.	0.14%	—

However, it seems very likely that the iron peak was retarded in its progress through the column by adsorption so that its position did not truly indicate molecular size. Adsorption of iron in this way would increase the proportion of free dextran detected.

The ultracentrifugation experiment showed that the iron-dextran complex has a molecular or particle size much greater than that of γ -globulin. Muir and Golberg⁴ showed by electron microscopy the presence of electron-dense particles 2–3 μ in diameter, and the particulate nature of the complex was confirmed by an electron micrograph of one of the fractions (fraction 10, Fig. 2) which showed particles approximately 3–4 μ in diameter.

The ultrafiltration experiments showed conclusively that a large proportion of uncombined dextran (42.2 per cent) was present. By this means it was possible to remove the latter, leaving what was presumably a solution containing only iron-dextran complex. The ratio of iron to dextran in this solution was 0.418:1, which is slightly higher than that calculated for one iron atom per anhydroglucose unit, in which the ratio is 0.346:1. The ratio corresponds with 2.4 parts of dextran to 1 part of iron.

The molecular weight of the dextran from which the preparation is made is little more than 5,000. In order to have a molecular weight greatly exceeding 150,000 and a particle size of 2–3 μ there must be considerable cross-linking or association of molecules to form the complex. Further investigations are being carried out on this aspect.

Electron micrographs of fraction 10 were kindly prepared and interpreted by Dr. A. T. Charles, Medical Research Council Unit for Research on the Experimental Pathology of the Skin, University of Birmingham.

PENICILLINASE SYNTHESIS CONTROLLED BY INFECTIOUS R FACTORS IN ENTEROBACTERIACEAE

By DR. NAOMI DATTA

Department of Bacteriology, Postgraduate Medical School, London

AND

DR. POLYXENI KONTOMICHALOU

Department of Bacteriology, Clinic of Therapeutics, University of Athens

RESISTANCE to antibacterial drugs may be transferred from one bacterium to another among the Enterobacteriaceae by direct cell-to-cell contact (conjugation). This transferable resistance was discovered in Japan¹⁻³ and later reported in Britain⁴ and in Germany⁵. The infectious agents which mediate the transfer are known as resistance factors (*R* factors) and have been shown to be extra-chromosomal genetic elements, or plasmids, consisting of deoxyribonucleic acid^{3,6}. *R* factors are transferred by conjugation between cells of many genera—all the Enterobacteriaceae⁷ as well as other Gram-negative bacilli such as *Vibrio*⁸, *Serratia*⁹ and *Pasteurella*¹⁰. The resistance conferred by the *R* factors first described was against the four drugs streptomycin, tetracycline, chloramphenicol and sulphonamides, usually of all four together, but sometimes against three, two or one of them. Lebek⁵ described an *R* factor which conferred resistance to neomycin and kanamycin, as well as to the original four drugs.

That genetic information for resistance to penicillins, including ampicillin, could be carried on *R* factors was found independently in Britain¹¹, in Greece (Kontomichalou, unpublished data) and in Switzerland (Lebek, personal communication). Preliminary experiments¹¹ suggested that infectious resistance to penicillins was dependent on the production of a penicillin-destroying enzyme. We now report that this enzyme is penicillinase (*EC* 3.5.2.6), since on incubation with benzylpenicillin it liberates penicilloic acid. We therefore present evidence that the genetic information for the biosynthesis of penicillinase is carried on the *R* factor.

R factors and host bacteria. The *R* factors we have studied are listed in Table 1. The host bacteria in which penicillin resistance was studied were *Escherichia coli* K12, *E. coli* strain TEM the *R* factor of which had been eliminated by acriflavine treatment¹², and *Salmonella typhi* strain 152, a drug-sensitive strain isolated in Greece in 1962.

Table 1

R factor	Species in which isolated	Year of isolation	Place of isolation	Pattern of infective resistance
R _{TEM}	<i>Escherichia coli</i> , strain TEM	1963	Athens	A S
R ₁₅₁₅	<i>Salmonella typhimurium</i> (ref. 11) phage type 1a	1962	Brighton	A S T Su
R ₇₂₆₈	<i>Salmonella paratyphi</i> B	1963	London	A C Su K

Species resistant to: A, ampicillin; C, chloramphenicol; S, streptomycin; Su, sulphonamides; T, tetracycline; K, kanamycin.

The R factors were transferred from their original hosts to the bacterial strains used experimentally by growing resistant and sensitive cultures together in broth, and plating on medium selective for the recipient organisms, but incorporating ampicillin. For example, in transferring resistance from *Salmonella* to *E. coli* the mixtures were plated on minimal agar with lactose as sole C source and with ampicillin, 25 µg/ml.

Stability of R factors in their bacterial hosts. Cultures carrying R factors contain a variable proportion of drug-sensitive cells from which the factor has been entirely lost^{1,2}. The rate of loss varies greatly between different R factors and between different hosts. The rate of loss of all the 3 R factors we describe here was 1:1,000 cell divisions or less, in the original hosts as well as in *E. coli* K12, *E. coli* TEM and *S. typhi* 152.

'Training' to ampicillin resistance. The sensitive host bacteria, *E. coli* K12 and *E. coli* TEM, were 'trained' to become resistant to ampicillin by passage on nutrient agar gradient plates containing increasing concentrations of ampicillin. These laboratory-trained resistant cultures were compared with R factor infected cultures in the experiments described later (see Table 2).

Extraction of enzymes. No penicillinase was found in supernatant fluid from our cultures carrying R factors. Highest yields of enzyme were from suspensions broken ultrasonically with a Mullard drill. Fast centrifugation (105,000g for 2 h) of the ultrasonicates left all activity in the supernatant. Methods of extracting enzyme without disrupting the cells, such as by toluene treatment, ethylenediamine tetraacetic acid (EDTA) at pH 8 (ref. 13) or EDTA + 20 per cent (w/v) sucrose at pH 8 (ref. 14), liberated up to 35 per cent of the penicillinase activity found in ultrasonicated preparations. Extraction of the enzyme by these methods, which leave the cell membrane intact, indicates that, like some other degradative enzymes in *E. coli*¹⁴, these penicillinases are 'periplasmic' enzymes.

Penicillinase assays. The cultures with and without R factors (R+ and R-) were assayed iodometrically for

hydrolysis of benzylpenicillin, ampicillin and cephaloridine the latter two drugs being chosen because of their clinical importance in treatment of infection caused by Gram-negative bacilli. 6-Amino penicillanic acid (6-APA) also used, because it had been found¹⁵ to be a highly effective antibiotic against at least one strain of penicillinase-producing Gram-negative bacilli.

Bacteria from exponential phase-aerated broth cultures were collected by centrifugation and the bacteria resuspended in distilled water, the volume being chosen according to the expected enzyme activity of the preparation. Assays were made using these suspensions untreated and after ultrasonic disruption. The method of assay was that of Perret¹⁶ as modified by Nevick¹⁷. Hydrolysis of cephaloridine was measured similarly to that of benzylpenicillin and ampicillin and 6-APA, except that the amount destroyed was calculated on a basis of 1 mole hydrolysed cephaloridine being equivalent to 4 equivalents of iodine¹⁸. The enzyme activities of the preparations were expressed in the units defined by Pollock and Torriani¹⁹: 1 unit equivalent to 1 µmole penicillin hydrolysed/h at 30° at pH 7.0.

Levels of resistance to penicillin, ampicillin, cephaloridine and 6-APA. The presence of R factors in the cultures was recognized by their greatly increased resistance to ampicillin. We measured the levels of resistance of our cultures against the four drugs used as substrates in the enzyme assays. Aerated broth cultures in the exponential phase were diluted to contain approximately 10⁷ organisms/ml and 10⁸ organisms/ml. These suspensions were dropped from calibrated pipettes on nutrient agar plates incorporating serial dilutions of the drugs under test. The heavy suspension gave confluent growth on drug-free control plates; the light suspension yielded isolated colonies. The minimal inhibitory concentration (M.I.C.) recorded was the lowest which prevented visible growth.

The M.I.C.s and the results of enzyme assays are summarized in Table 2.

From Table 2 the following observations may be made:

(1) The host *E. coli* cultures, both K12 and TEM without R factors, were drug-sensitive and had very low but just measurable, hydrolytic activity against benzylpenicillin and cephaloridine, but none against ampicillin or 6-APA. *S. typhi* 152 was considerably more sensitive to benzylpenicillin and ampicillin than our *E. coli* strains. No penicillinase was detected in *S. typhi* 152 without R factors, but it may, nevertheless, possess very low activity since we did not assay highly concentrated suspensions

Table 2. LEVELS OF RESISTANCE AND PENICILLINASE ACTIVITY CONFERRED BY R FACTORS

R factor	Host bacteria	Minimal inhibitory concentration (μg/ml medium)					Enzyme activity (units/h/mg dry weight)				
		Inoculum (No bacteria/ml.)	Benzylpenicillin	Ampicillin	Cephaloridine	6-APA		Benzylpenicillin	Ampicillin	Cephaloridine	6-APA

—, No detectable activity. Lowest detectable activity: in *E. coli*, 0.05 units/h/mg dry wt; in *S. typhi*, 0.5 units/h/mg dry wt.

is organism, as we did for the non-pathogenic ones. 'raining' of our *E. coli* cultures on ampicillin did not lead to their developing appreciably higher hydrolytic activity against any of the four substrates, and there was still no detectable hydrolysis of ampicillin or 6-APA.

(2) Acquisition of *R* factors by the cultures resulted in greatly increased resistance to benzylpenicillin, ampicillin and 6-APA, and greatly increased hydrolytic activity against all four drugs tested. The levels of drug-resistance obtained by the *R* + bacteria were different for each of the three *R* factors studied. The levels of resistance were early related to penicillinase activity, the most resistant having highest penicillinase activity and the least resistant, the least.

(3) Different host bacteria carrying the same *R* factor showed rather similar penicillinase activities. With all three factors, *E. coli* K12 showed slightly but consistently higher activity than *E. coli* TEM and, where tested, *S. typhi* 152 showed even higher activity, but these differences were not accompanied by differences in the levels of drug-resistance.

(4) Whole *R* + cell suspensions, assayed for hydrolysis of penicillin and ampicillin, gave low levels of activity, indicating that the penicillinase was inaccessible to these substrates unless liberated by ultrasonic disruption (or any of the other methods already discussed). For cephaloridine and 6-APA, on the contrary, the difference in the rate of hydrolysis by whole cell suspensions and by ultrasonicated ones was small, indicating that for these substrates the permeability barrier excluding penicillin and ampicillin was not effective. Table 2 also shows that the *R* + cultures, although their hydrolytic activity against cephaloridine is raised to the same degree as that against benzylpenicillin and ampicillin, have not acquired nearly such a high degree of resistance to cephaloridine as to the penicillins.

(5) The *R* - cultures were more sensitive to ampicillin than to benzylpenicillin but the *R* + cultures were equally resistant to both.

Substrate profiles. The penicillinase activity of some of our cultures carrying *R* factors was assayed against a wider range of substrates than shown in Table 2 (see Table 3). The penicillinase produced by three different hosts infected by one *R* factor (*R*TEM) all showed similar substrate profiles. But when the penicillinases from one host (*E. coli* K12), infected with three different *R* factors, were compared they showed interesting differences in substrate profiles. Penicillinase from *E. coli* K12 with factor *R*7258 had a similar substrate profile to that with *R*TEM, but with *R*1818 the profile was quite different; with *R*1818 cloxacillin was hydrolysed as rapidly as benzylpenicillin and phenoxymethyl- and phenoxypentyl-penicillin considerably more rapidly still.

Induction. Tests for inducibility of penicillinase have so far been limited to the examination of *E. coli* K12 carrying factor *R*1818. When methicillin was added to a growing culture no increase in penicillinase activity was observed.

Discussion. The synthesis of penicillinase by our cultures carrying *R* factors appears to be under the direct genetic control of the *R* factors. It might be argued that,

since the host cultures without *R* factors themselves produce some penicillinase, the *R* factors act only to remove a repressor mechanism and so increase penicillinase activity; extracts of our *R* + cultures differ, however, from those of our *R* - cultures not only in their greatly increased penicillinase activity, but also in having high activity against ampicillin and 6-APA. We believe, therefore, that the *R* + cultures synthesize penicillinases which are not present in the *R* - cultures. Penicillinases from our *R* - *E. coli* strains resemble in their substrate range those of *E. coli* strains described by Smith and Hamilton-Miller^{20,24}, while the same *E. coli* strains, carrying *R* factors, synthesize penicillinases with very different substrate profiles.

The penicillinases synthesized by *E. coli* K12 carrying factors *R*TEM and *R*7258 resemble one another in their substrate profiles, although not in their levels of activity. Their substrate profiles resemble those of extracts of *Aerobacter* (*Klebsiella*) *cerogenes* described by Smith and Hamilton-Miller²⁰. We do not yet know whether each enzyme is specific to its *R* factor or whether these two factors both determine the synthesis of the same enzyme, each at a characteristic rate. The penicillinase of factor *R*1818 differs markedly from the others, and from all penicillinases so far described, in hydrolysing cloxacillin as rapidly as benzylpenicillin and in hydrolysing phenoxymethyl and phenoxypentyl penicillins considerably faster still.

The parallelism between the levels of drug-resistance and the penicillinase activities conferred by the different *R* factors strongly suggests that the resistance was the direct result of the presence of penicillinase in the cells. The increase of drug-resistance with drug-hydrolysis was much less with cephaloridine than with the penicillins; thus the penetration of a drug into the cell may increase the antibacterial effectiveness of the drug, as indicated by Hamilton-Miller¹⁶; however, in spite of the permeability of the cells to 6-APA, the latter was not a highly effective antibiotic against our strains.

It is especially interesting that penicillinase biosynthesis can be controlled by infective extrachromosomal elements in the Enterobacteriaceae, since it is known that penicillinase in staphylococci is controlled by comparable, though non-infective, plasmids²¹⁻²³.

We thank Mrs. Roma Pride for her assistance and Dr. M. H. Richmond for his advice.

DEOXYRIBONUCLEIC ACID SYNTHESIS IN CULTURED HUMAN CELLS AND ITS BEARING ON THE CONCEPTS OF ENDOREDUPPLICATION AND POLYPLOIDY

By DR. URSULA MITTWOCH, MRS. KUSUM P. LELE and W. S. WEBSTER

Galton Laboratory, University College, London

THE synthesis of deoxyribonucleic acid (DNA) is a prerequisite for mitosis, but it is now known that the two processes are essentially separate^{1,2}. If DNA synthesis occurs in excess of requirements for the production of new cells, some of the existing cells will become polyploid. We wish to present some data showing that this happens in human fibroblast-like cells grown in tissue culture.

The cells originated from skin biopsies which were cultured according to the technique of Harnden³. Culture *C*, which had been growing for five weeks and had been sub-cultured 4 times, had an apparently normal female karyotype, although the cells originated from a male; culture *D*, grown also for 5 weeks and sub-cultured three times, had two X-chromosomes and a structural abnormality of a small autosome, which will be described by Crawford and Lele⁴. After trypsinization, the cells were allowed to grow on cover slips for about 25 h, when they were fixed in 95 per cent ethanol (0.5 h), hydrolysed in N hydrochloric acid at 60° C (10 min) and stained with Feulgen (1 h). The cover slips were mounted on glass slides. The light absorbed by individual nuclei was measured with an integrating microdensitometer (Barr and Stroud). This instrument was designed by Deeley⁵. The amount of light absorbed by Feulgen-stained nuclei may be regarded as proportional to the amount of DNA present. For diagrammatic representation, the DNA values were converted into logarithms to the base 2, thus separating any value from double its value by one unit. The lengths of the two main nuclear axes were measured with an eyepiece micrometer and the areas were converted into μ^2 with the help of a stage micrometer. From each culture, 1,000 nuclei were measured.

The DNA values, in arbitrary units, of interphase nuclei are shown in Fig. 1. The number of nuclei scored as in mitosis was 87 in culture *C* and 83 in culture *D*. But although the mitotic rates were similar in both cultures, the distributions of DNA values are clearly very different. The approximate number of cells belonging to each DNA class are given in Table 1. Whereas in culture *C* more than two-thirds of the nuclei fall into the diploid class, only about one-third of the nuclei in culture *D* are diploid, and two-thirds are either in the process of DNA synthesis or, having completed this, are polyploid. Although the size of the nuclei varies even within the same DNA class, as is evident from the standard deviations, it will be seen that the mean nuclear areas increase step-wise with increased amounts of DNA. As the nuclei are very flat, their areas may be regarded as proportional to their volumes. The figures in Table 1 show that the increase of about 12 per cent in the average nuclear area of culture *D* compared with culture *C* can be accounted for by a higher incidence of polyploid cells.

It must be emphasized that a high degree of polyploidy is characteristic of the nuclei in interphase only. The

incidence of polyploid mitoses was only about 2–3 per cent in both cultures. Wolman *et al.*⁶ reported a similar incidence of tetraploid mitoses in tissue cultures during the period of rapid cell division; the incidence of tetraploid mitoses increased with the decline of cell divisions in the culture and following infection with simian virus 40. Polyploid mitoses are common in many tumours, as was shown by Levan⁷, and Atkin⁸ concluded that for most human tumours the ploidy indicated by DNA values in interphase is in agreement with that obtained from chromosome counts in mitosis. It appears likely, however, that this relationship does not apply to normal dividing tissues, in which the incidence of polyploidy among cells in interphase may be much higher than in mitotic cells.

There can be little doubt that polyploid interphase cells occur also *in vivo*. Thus Swift found DNA values of different multiples in various tissues of the mouse⁹ as well as in plants¹⁰; Swartz¹¹ reported different DNA

Fig. 1. DNA values in arbitrary units, log scale, of fibroblast-like cells. (a) Culture *C*, (b) culture *D*

Table 1. MEAN NUCLEAR AREAS IN CELLS WITH DIFFERENT DNA VALUES

	Culture <i>C</i>			Culture <i>D</i>

asses in cells of human liver, and Klinger and Schwarzer¹² in human amnion epithelium and foetal liver.

It was shown by Howard and Pelc¹³ that in rapidly dividing cells of the bean, *Vicia faba*, the interphase between two mitoses consisted of three stages: (1) a rest growth period, *G*₁; (2) the period of DNA synthesis, *S*; (3) a second growth period, *G*₂, leading to mitosis. It is becoming clear, however, that mitosis is not a necessary consequence of *G*₂. Thus, Gelfant¹⁴ found that epidermal cells of mice fell into two classes, those in which *G*₂ was followed by mitosis and others which appeared to be blocked in the *G*₂ stage and stayed there for a long time; and Patau and Das¹ have presented evidence that cells of the tobacco plant which have synthesized DNA are ambivalent in the sense that, according to circumstances, they may either enter mitosis or go through another DNA synthesis.

It is clear that DNA synthesis unaccompanied by mitosis is synonymous with the process which has been described as 'endomitosis' or 'endoreduplication'. The term 'endomitosis' is due to Geitler¹⁵, who observed that in the nuclei of insects of the class Heteroptera, chromosome-like structures appeared which apparently underwent an abortive mitosis. Afterwards such nuclei became polyploid. The most highly polyploid nuclei were those of the salivary gland cells, which became 64 ploid during the first instar and at least 1,024 ploid in the imago. It should be emphasized that the concept of endomitosis arose at a time when it was not yet recognized that the process of chromosome replication is essentially separate from the mitotic process. Consequently, Geitler¹⁶ distinguishes between those cases of endopolyploidy in which the nuclei show some resemblance to nuclei in mitosis and others in which polyploidy arises without any visible symptoms apparently at a 'sub-microscopical level'. A similar distinction was made by Levan and Hauschka¹⁷, who limited the term 'endomitosis' to nuclei which seemed to show conspicuous activity inside the nuclear membrane and gave the name "endoreduplication" to the process of chromosome replication which went on concealed during the despiralized stage. It would appear that with our present state of knowledge this distinction has lost its importance. Furthermore, the realization that mitosis does not result in chromosome replication has made the term 'endomitosis' self-contradictory, as has already been suggested¹. The term 'endoreduplication', therefore, seems preferable to describe the process of chromosomal replication which, in the absence of mitosis, leads to polyploidy. The term 'endopolyploidy' is useful to distinguish polyploidy which has arisen in this way from polyploidy originating by nuclear fusion.

If nuclei which have undergone at least two series of replications afterwards undergo mitosis, the duplicated chromosomes characteristically occur in pairs (Fig. 2). Polyploid mitoses with paired chromosomes were first demonstrated by Levan¹⁸ in plant cells which had become polyploid following treatment with growth hormones, and Levan and Hauschka found an abundance of such figures in ascites tumours of the mouse. Polyploid mitoses with paired chromosomes in human tissue culture cells derived from skin were first described by Fraccaro *et al.*¹⁹. However, the incidence of such cells in tissue culture tends to be low. As pointed out above, the incidence of all polyploid mitoses in rapidly dividing cultures is only a few per cent, and only a small percentage of polyploid mitoses have paired chromosomes. The significance of such cells is clearly that they represent the first mitotic division following endoreduplication; thus the twice-duplicated chromosomes are still more or less *in situ*, having not yet become dispersed by the movements of cell division.

The difference in the incidence of polyploidy in interphase and mitotic nuclei directs attention to the problem of nomenclature. Some authors have tried to evade the concept of polyploidy in interphase by ascribing to cells which have duplicated their DNA a certain *C* value¹⁰. Thus a diploid cell which has completed DNA synthesis would be 4*C*. This nomenclature appears to be unsatisfactory for a number of reasons. The symbol *C* in this context does not stand for any definite term. Patau and Swift²⁰ wrote: "It is also generally agreed upon that these multiples, usually terms of the series *C*, 2*C*, 4*C*, show a close relation to the chromosome or rather chromatid number. *C* is apparently always found after the second meiotic division". There is, however, as yet no way of counting either chromosomes, chromatids or centromeres in interphase nuclei. As regards the apparent ambivalence of cells which have undergone DNA synthesis, there can be no logical objection to the statement that a cell becomes tetraploid prior to its giving rise to two diploid ones; while it is becoming clear that a substantial proportion of cells with duplicated DNA contents do not undergo mitosis but remain as interphase cells of larger size. Large interphase nuclei have been recognized as polyploid for a long time. There appears to be no reason to change this concept now that it is possible to obtain an accurate assessment of the degree of polyploidy by measuring their DNA contents.

Geitler¹⁶ wrote that, owing to the belief in the constancy of chromosome numbers, the phenomenon of endopolyploidy was neglected. It now appears that the adherents of both apparently conflicting views were right: while

Fig. 2. Tetraploid mitoses in human fibroblast-like cells. (a) Usual type; (b) with paired chromosomes, as is characteristic for the first mitosis following endoreduplication. (By courtesy of Dr. Joy Delhanty)

dividing cells have a strong tendency to retain the diploid chromosome number, a substantial proportion of cells become polyploid in interphase.

We thank Dr. Joy Delhanty for contributing Figs. 2a and b. The integrating microdensitometer was provided by the Central Research Fund, University of London. The work was also partly supported by grant HD-00500-04 from the U.S. Public Health Service.

PROTEIN SYNTHESIS IN RETICULOCYTES MATURING IN VIVO

By DR. PETER T. ROWLEY

Department of Medicine, Stanford University School of Medicine, and Medical Service, Veterans Administration Hospital, Palo Alto, California

THE transition from mammalian reticulocyte to mature erythrocyte is marked by the loss, not only of the stainable reticular material, but also of the ability to synthesize protein. Recently, the site of protein synthesis, not only in reticulocytes but also in a wide variety of cells, has been shown to be aggregates of ribosomes called polyribosomes¹⁻³. The present search for the cause of the declining rate of protein synthesis in the maturing reticulocyte was undertaken in the hope that the explanation might contribute to a general understanding of the rate determinants of mammalian protein synthesis.

Two methods have been previously used to examine reticulocyte maturation⁴. One is the comparison of cells from an animal at various times following an erythropoietic stimulus; a cell population so derived, however, is far from homogeneous. The second is the investigation of cells aged under controlled conditions *in vitro*. Using the latter method, Bertles and Beck⁵ showed that maturation *in vitro* is associated with a conversion of RNA into products of low molecular weight, which are released from the cell. Marks *et al.*⁶ by sucrose gradient analysis, and Rifkind *et al.*⁷ by electron microscopy, showed that maturation *in vitro* is associated with a progressive disaggregation of polyribosomes to smaller clusters and single ribosomes.

The present investigation of reticulocyte maturation was prompted by the report of a method to separate red cells by age using density gradient centrifugation⁸. This method provided a means of determining whether the above conclusions about cells matured *in vitro* also applied to cells of different age removed from the same animal at the same time.

Specifically, answers were sought to two questions: (1) how does the rate of protein synthesis in the maturing reticulocyte vary with age, and (2) which component of the protein synthetic apparatus fails? Protein synthetic rates were determined for young and old reticulocytes (a) as whole cells, (b) in cell-free systems derived from each, and (c) in cell-free systems in which young and old fractions were interchanged. Evidence is presented that the decline in protein synthesis in the maturing reticulocyte correlates primarily with the decline in the quantity of polyribosomes per cell.

The density of the red cell increases with age. This fact enabled Leif and Vinograd⁸ to separate erythrocytes according to age on a linear density gradient of bovine serum albumin. They verified the method for rabbit erythrocytes by the serial analysis of cells obtained from a rabbit injected with ⁵⁹FeCl₃.

Using position in such a gradient as a measure of age, protein synthesis in rabbit reticulocytes was determined

as a function of age, first in whole cells. The experiment shown in Fig. 1 indicates that, as the cells get denser and occupy a lower position in the gradient, they are also less active in protein synthesis. In this experiment, the top sixth of the cell population was 240 times as active as the bottom sixth. What accounts for this difference between old and young reticulocytes?

To determine this, 'young' and 'old' reticulocytes were separately pooled from the top and bottom halves respectively, of an albumin-density gradient. The samples contained 97 and 94 per cent reticulocytes respectively, the mature red cells from the initial sample (60 per cent reticulocytes) having formed a pellet at the bottom of the gradient tube. Both whole-cell and cell-free syntheses were examined. As whole cells, the young cells were 2.5 times more active than the old cells (Fig. 2)

Fig. 1. Distribution and protein synthetic activity of reticulocytes separated by age on a density gradient. A New Zealand albino rabbit was injected subcutaneously with phenylhydrazine HCl (12.5 mg/kg the first day, then 10 mg/kg for four days) and bled on the sixth day. Washed, packed cells 2.5 ml., diluted to 5 ml. with saline, were layered on to a 50-ml. linear density gradient (20-35 per cent, w/w) of bovine serum albumin in saline (ref. 8) and centrifuged at 20,000 r.p.m. in a rotor type 25-2 in the Spinco Model 'L-2' ultracentrifuge for 30 min. Six fractions were collected and the cells recovered by dilution with saline and centrifugation at 2,000g for 5 min. From each fraction, 0.05 ml. packed cells were incubated with L-leucine-¹⁴C (3.56 × 10⁶ c.p.m./μmol.) 9 μmol., other amino-acids in the ratio of Lingrel *et al.* (ref. 11) 96 μg. glucose 0.88 μmol., sodium citrate 0.18 μmol., Fe(NH₄)(SO₄)₂ 2 μmol., NaCl 16.8 μmol., MgCl₂ 0.31 μmol., NaHCO₃ 0.26 μmol., 0.04 ml. of the same rabbit's plasma and tris 3.6 μmol. at pH 7.4 in a total volume of 0.23 ml. at 37° C for 1.5 min. The cells were then washed and lysed by the addition of 0.45 ml. of 0.01 M KCl, 0.003 M MgCl₂, 0.01 M Tris-Cl, pH 7.4, containing 100 units of heparin per ml., and the membranes removed by centrifugation at 10,000g for 15 min. The acid-precipitable radioactivity of the membrane-free lysate was determined, after washing on 'Millipore' filters, using a liquid scintillation counter.

Fig. 2. The membrane-free lysates from the experiment described in Fig. 1 were used. Of the six fractions, only the analyses of fractions 2 ('old') and 6 ('young') are reproduced. Membrane-free lysate, 0.2 ml., was layered on to a 4.8-ml. gradient of sucrose, 10–30 per cent in 0.01 M KCl, 0.003 M $MgCl_2$, 0.01 M $tris\text{-}Cl$, pH 7.4, containing 100 units of heparin per ml. and centrifuged at 40,000 r.p.m. in a 'SW-39' rotor in a Model L-2 Spino ultracentrifuge for 1 h. Fractions, 0.25 ml., were analysed for absorbance at 260 $m\mu$ using a Beckman 'DU' monochromator and a Gilford 'Model 220' photometer, and for radioactivity using a liquid scintillation counter after addition of 10 ml. Bray's solution (ref. 12).

Protein synthesis by fractions from young and old reticulocytes are compared in Table 1 (incubations 1 and 2). The fractions from young cells were also several (3.8) times more active 'per cell' (see footnote) than fractions from old cells. The relative contribution of ribosomes and supernatant was determined by interchanging young and old fractions (incubations 3 and 4). The mixed incubation containing young ribosomes (No. 3) was 70 per cent as active per cell as the incubation of the wholly young fractions (No. 2), whereas the mixed incubation containing old ribosomes (No. 4) was scarcely more active than the incubation of wholly old fractions (No. 1). Hence the ribosomes were largely the rate-determining fraction.

The young cells contained more ribosomal material than the old cells. Expressed as optical density units at 260 $m\mu$, the young cell averaged 6.24×10^{-9} units and the old cell 2.49×10^{-9} units. The greater activity of the ribosomal fraction from the young cells is due, however, not solely to their greater quantity of ribosomal material per cell, but also to a more active type of ribosomal material, as shown by a higher rate of protein synthesis per O.D. unit of ribosomes (Table 1).

Since protein is synthesized chiefly on polyribosomes, one might suppose that the principal difference between the ribosomal fractions of young and old cells would be in the quantity of polysomes. To test this hypothesis, young and old cells were incubated whole with radioactive amino-acids, and their lysates analysed on sucrose gradients. Young and old whole-cell fractions, separated in the experiment described in Fig. 1 and differing 10-fold in their whole-cell synthetic rate, were used. The results are shown graphically in Fig. 2 and quantitatively in Table 2. Cell for cell, the two striking differences are in the quantity of polyribosomes (old = 20 per cent of the young) and in the radioactivity in the polyribosomes

(old = 14 per cent of the young). Since the quantity and radioactivity of polyribosomes are comparably reduced, their specific activity ($\mu\text{mol. leucine bound per optical density unit of polysome}$) showed only a modest decrease (old = 66 per cent young). The quantity of single ribosomes (Table 2) showed only modest reduction. The significance of the increase in average release time is not known.

Maturation of the reticulocyte is then marked by two processes, a decrease in the total quantity of ribosomes and a disproportionate decrease in the quantity of polyribosomes, as described by Rifkind⁷ for maturation *in vitro* and in a peritoneal diffusion chamber. The cause of neither of these processes is known. Investigations of ribonuclease activity in lysates of young and old cells are in progress.

Maximal recovery of polysomes requires minimizing ribonuclease action during isolation. In controlled experiments, the use of heparin, a known inhibitor of ribonuclease⁹, in the lysing solution and in the sucrose gradient increased polysome yields. Lysis by brief osmotic shock, described by Marks *et al.*¹ as specific for red cells, may also have been of value, since white cells have much more ribonuclease than red cells¹⁰.

In summary, the most striking change in the maturing reticulocyte as haemoglobin synthesis decreases is a decline in the quantity of polyribosomes per cell. This conclusion has been previously reached for cells maturing *in vitro* or in a peritoneal diffusion chamber. It has now been documented for cells of different age removed from the same animal at the same time.

Since this account was prepared, a report has appeared by Glowacki and Millette (*J. Mol. Biol.*, 11, 116; 1965)

Table 1. PROTEIN SYNTHESIS BY FRACTIONS FROM YOUNG AND OLD RETICULOCYTES

Source of fractions:	1	2	3	4
Ribosomes	Old	Young	Young	Old
Supernatant	Old	Young	Old	Young
Incorporation into protein:				
$\mu\text{mol. leucine}$	155	486	342	172
$\mu\text{mol./}10^6$ cells*	166	639	450	185
$\mu\text{mol./O.D.}_{260}$ ribosomes	53	82	57	59

* The calculation of $\mu\text{mol./}10^6$ cells involved the number of cells which provided the ribosomes for the incubation.

Blood (30 ml.) from a New Zealand albino rabbit (2.8 kg), treated with phenylhydrazine HCl (10 mg/kg) on the preceding 5 days, was passed through a tightly packed column of 'Deponol'-treated nylon fibres (3 g) at room temperature to remove granulocytes (ref. 13) and centrifuged (2,000g, 5 min). Packed cells (2.5 ml.) were separated according to age by density gradient centrifugation (Fig. 1) and the gradient divided into two parts, an upper ('young') and lower ('old'), containing an equal volume (1 ml.) of cells after packing. Packed cells (0.8 ml.), young (4.57×10^6 cells) or old (5.6×10^6 cells), were separately lysed by the addition of 3.2 ml. 0.005 M $MgCl_2$, followed in 30 sec by 0.8 ml. 1.5 M sucrose–0.15 M KCl (ref. 1). Fractions were prepared and cell-free synthesis carried out in a manner similar to that of Allen and Schweet (ref. 14). Lysates were centrifuged at 15,000g, 10 min. The supernatants were re-centrifuged at 8,000g, 1 h. Pellets were rinsed with 0.05 ml. 0.25 M sucrose, 0.0175 M KH_2PO_4 , 0.002 M $MgCl_2$, homogenized in 2 ml. of the same, and ribosomes and supernatants were re-centrifuged as before. The final pellets were homogenized in 0.3 ml. 0.25 M sucrose in glass homogenizers by hand, the suspensions re-centrifuged at 15,000g, 5 min, and the final supernatants used as 'ribosomes'. Each incubation (0.15 ml.) contained: in μmoles , $tris\text{-}HCl$, pH 7.5, 56; KCl, 50; glutathione, 20; creatine phosphate, 10; ATP, 1; GTP, 0.25; $MgCl_2$, 5; $^{14}C\text{-L-leucine}$, 3.55×10^3 c.p.m./ $\mu\text{mol.}$, 0.005; 18 other L-amino-acids, 2.1 μg total, in the ratio of Lingrel *et al.* (ref. 11); creatine kinase, 0.12 mg; supernatant, 0.04 ml.; and ribosomes, 0.05 ml. After 20 min at 37°, cold water was added and the material insoluble in 5 per cent trichloroacetic acid was washed and counted on 'Millipore' filters in a liquid scintillation counter. A control incubation of young fractions to which $^{14}C\text{-L-leucine}$ was added after incubation incorporated a total of 80 c.p.m. Optical density of ribosome suspensions at 260 $m\mu$ was determined in 0.01 M NaOH.

Table 2. POLYSOMES FROM YOUNG AND OLD RETICULOCYTES

	Per 10^6 cells		
	Young	Old	Old/Young
Whole cell synthetic rate $\mu\text{mol. leucine}$ incorporated/1.5 min	305	27.7	9.1%
O.D. ₂₆₀ in polysomes	5.08	1.04	20%
O.D. ₂₆₀ in single ribosomes	5.60	4.00	71%
Polysome-bound leucine, $\mu\text{mol.}$	31.8	4.3	14%
Specific activity of polysomes: $\mu\text{mol.}$			
leucine bound/O.D. ₂₆₀ $m\mu$	6.25	4.14	66%
Average release time, min*	0.156	0.233	149%

* Average release time is the average time radioactive amino-acid is bound to polysomes before release into supernatant: (leucine in polysomes/total acid-insoluble leucine) \times 1.5 min. The data in this table were calculated from the data in Fig. 2.

describing experiments similar to some of those reported here. They also incubated intact rabbit reticulocytes, separated by age using density gradient centrifugation, with radioactive amino-acids and analysed the lysates on sucrose gradients. Despite several differences in technique, both their results and ours indicate that the decline in protein synthesis with maturation is accompanied by, cell for cell, a decrease in total ribosomal material, a decrease in the fraction present as polyribosomes without a decrease in the apparent size of the aggregate, and some decrease in the specific activity of the polyribosomes. From available data, the last mentioned could be due to either a decrease in activity of all polysomes or to a growing fraction of inactive polysomes.

I thank Josephine Morris, Michael Johnson, Hilary Cheadle and Myrna Sproul for their assistance, and Dr. Paul Berg for advice.

NUCLEO-CYTOPLASMIC INTERACTIONS IN THE RAT LIVER CELL

By E. R. GODWIN, DR. K. R. REES, DR. G. F. ROWLAND and J. S. VARCOE

Department of Chemical Pathology, University College Hospital Medical School, London, W.C.1

ONE aspect of the investigation of nucleo-cytoplasmic interaction in the liver cell is the study of the intracellular movement of proteins. This requires the application of chase-labelling techniques to an *in vitro* system using a sufficiently large quantity of tissue to permit subcellular fractionation at the end of the experiment.

Whole-liver cell preparations would be ideal for these experiments, but preparations that have been described have a low yield of cells and these often have impaired metabolic activity. A metabolically active liver cell preparation such as the slice has a disadvantage in that only a limited number of slices can be prepared from each liver. For these reasons it was decided to explore the 'tissue chop' technique as a method of producing a large amount of a cellular preparation of liver.

McIlwaine and Buddle¹ designed a mechanical tissue chopper and showed that the respiration of tissue 'chops' of cerebral cortex was within 3 per cent of the respiration of ordinary hand-cut slices. They also demonstrated that such a chopper would produce tissue chops from small quantities of a whole range of tissues such as heart, liver, spleen and kidney.

In the present investigation it was necessary to be able to handle quickly at least 7 g of liver and often more. A tissue chopper was made, based on that of McIlwaine and Buddle, modified, however, to take larger quantities of tissues by increasing the size of the chopping platform and the blade. For each experiment two male rats weighing 150 g were killed by cervical fracture and the livers rapidly removed into ice-cold Krebs-Ringer-phosphate, pH 7.3 (Umbreit, Burris and Stauffer²), containing 0.1 per cent glucose. The lobes were then carefully trimmed to give slices of liver 2–5 mm. thick and chopped in two directions. The device was set to chop at intervals of 0.3 mm, thus producing minute columns of liver. The columns from 10 to 15 g liver were suspended in 30–50 ml. cold Krebs-Ringer-phosphate and allowed to sediment. The supernatant fluid containing broken cell debris was decanted and the chopped liver preparations washed three more times with cold Krebs-Ringer-phosphate before being finally suspended in Krebs-Ringer-phosphate plus glucose (30 ml. per 6–8 g chopped liver) and transferred to 100 ml. conical flasks for incubation. 10 μ c. of ¹⁴C-leucine was added to the flasks, which were then sealed with vaccine caps through which were passed syringe needles to allow for gas exchange. The chopped liver preparations were incubated for various times as required at 37° C under oxygen. After incubation

the liver suspensions were cooled in crushed ice and washed by decantation and resuspension twice in a solution 0.5 per cent w/v non-radioactive leucine in 0.25 M sucrose and then twice in 0.25 M sucrose. The liver preparations were finally resuspended in 0.25 M sucrose and the suspensions divided in two. One half was homogenized in Potter-Elvehjem homogenizer for preparation of mitochondria, microsomes and cell sap as described by Schneider³. To the other half, calcium chloride was added to a final concentration of 5 mM and the suspension homogenized in the hand-operated homogenizer for preparation of nuclei as described previously by Rees and Rowland⁴.

Fig. 1. Time-course of incorporation *in vitro* of 1-¹⁴C DL-leucine into proteins of subcellular fractions during incubation of chopped liver preparation. Results are the means from three experiments.

Fig. 2. Specific activities (SA) of sub-cellular fractions relative to specific activity of homogenate during the 'chase-labelling' period of the experiments shown in Table 1. The results are the means from four experiments.

By incubating a suspension of chopped liver in a Krebs–phosphate the time-course of ^{14}C leucine incorporation into the various subcellular fractions was examined. Fig. 1 shows the result of such an experiment. It is of particular interest to note that whereas at 40 and 60 min the cell sap proteins are more highly labelled than nuclear proteins, at earlier times this is not the case.

Several experiments of the 'chase-labelling' type were carried out in the following manner. The chopped liver preparation was washed free of broken cells in Krebs–phosphate solution and divided into three roughly equal portions. The portions were all incubated at 37°C with ^{14}C leucine for 10 min. At this stage one portion was cooled in crushed ice while 100-fold excess of non-radioactive leucine was added to the other portions, which were allowed to continue incubating for a further 10 and 20 min, respectively, before cooling in ice also. The cooled liver suspensions were washed free of isotope and broken cells as already described and then homogenized and fractionated to yield the various subcellular components. Table 1 shows the results of a typical experiment carried out in this way. To correct for

variations in the degree of overall labelling in the three portions the results have also been expressed as a ratio of the specific activity of each subcellular fraction to the specific activity of the homogenate from which they were isolated, and the means of the ratios from all the experiments are given in Fig. 2. It may be seen from these results that there is an overall fall in the radioactivity of both the microsomal and mitochondrial protein during the 20 min 'chase' period, and there is a considerable rise in the radioactivity of cell sap protein during this time. The nuclear protein shows a considerable drop in radioactivity after the first 10 min of 'chase-labelling', but during the second half of the 'chase' period the radioactivity returns to its former level.

Table 1. INCORPORATION OF $1\text{-}^{14}\text{C}$ DL-LEUCINE BY SUSPENSIONS OF CHOPPED LIVER FOLLOWED BY 100-FOLD EXCESS UNLABELLED LEUCINE IN ORDER TO FOLLOW MOVEMENT OF LABELLED PROTEIN FROM SITES OF PROTEIN SYNTHESIS WITHIN THE LIVER CELL

Incubation time with ^{14}C -leucine	10 min	10 min	10 min
Incubation time with ^{14}C -leucine	+ 0 min	+ 10 min	+ 20 min
Total time	10 min	20 min	30 min
Tissue fraction	c.p.m. at infinite thickness	c.p.m. at infinite thickness	c.p.m. at infinite thickness
Homogenate	109	124	142
Nuclei	105	85	140
Mitochondria	77	57	65
Microsomes	232	195	208
Cell sap	68	112	188

Results are those of a representative experiment of a group of 4 similar experiments.

These findings are in agreement with those of Goldstein⁵ and Prescott⁶, whose autoradiographic investigations have shown similar movements of protein to and from the nucleus of *Amoeba proteus*. Goldstein has examined two types of nuclear proteins: proteins that migrate from the nucleus to the cytoplasm and those that do not migrate. He concluded that both types are synthesized in the cytoplasm, but his experiments do not entirely rule out the existence of a species of non-migratory proteins synthesized within the nucleus. There is at present no indication as to the function of these migratory proteins in the cell.

One possible interpretation of these results is that there may be a movement of labelled protein out of the nucleus into the cytoplasm during the early stages of incubation followed by a movement of protein in the reverse direction—from cytoplasm into the nucleus.

BIOLOGY OF THE CYTOPLASM

By DR. OLE A. SCHJEIDE, RUTH G. McCANDLESS and R. J. MUNN

Laboratory of Nuclear Medicine and Radiation Biology, Department of Biophysics and Nuclear Medicine, School of Medicine, University of California, Los Angeles

Cytoplasmic Nucleic Acids

ACCORDING to the scheme initially proposed by Gierer¹ and Noll *et al.*², messenger RNAs leave the cell nucleus to become individually associated with one or more ribosomes in the cytoplasm. Thereafter, the ribosomes assemble a specific protein by moving along the strand of messenger RNA, exposing by 3-base increments the codes for individual amino-acids which are linearly arranged thereon.

This concept has received abundant experimental verification from the work of Rich *et al.*³ and others⁴, and is entirely convincing for certain systems. However, many investigators have held that the foregoing mechanism constitutes only a fragment of the total protein synthesizing machinery of most of the cells of higher animals⁵.

Electron micrographs of rapidly metabolizing cells offer a unique insight to this problem, and in the past we

have exploited the oocytes, follicular cells and developing organ systems of the chicken in this regard. In a recent communication⁶ we reported the following observations which are pertinent to the question of how nuclear materials reach the cytoplasm and how they function therein.

(a) Nucleolar nucleic acid is often present in the form of small vesicles (300–400 Å diam.) possibly containing protein as well as nucleic acid. Considerable numbers of these vesicles are sometimes seen arrayed in double helical 'stacks' within the body of the nucleolus. The phenomenon may be peculiar to a given brief phase of activity or it may be that these bodies are commonly so dispersed but that fixation of nuclear materials proceeds too slowly to preserve the orientation in most cases.

(b) Strings of such vesicles are often seen outside the nucleolus, in the karyoplasm, one end of the string usually being in intimate association with the nuclear membrane.

(c) The vesicles closest to a nuclear 'pore' are observed to be markedly reduced in size.

(d) It appears that such smaller vesicles (microvesicles) emerge from the site of a nuclear 'pore' at the periphery of that pore—which is characterized by so-called 'annular rods'. The 'annular rods' appear to radiate into both nucleus and cytoplasm.

(e) It may be that the 'rods' consist of rows of very small vesicles which are continuously moving into the cytoplasm.

(f) In any event, the microvesicles assemble in the cytoplasm to form larger oval bodies which resemble the 'kinetosomes' of *Paramecium*⁷. At the magnifications afforded by the electron microscope we were using at the time, these bodies (1000–1500 Å smaller diam., up to 4000 Å larger diam.) appear to consist of a relatively dense membrane with regularly spaced outwardly projecting bristles (200–250 Å in length—200–250 Å apart) and a centrally located dark streak.

(g) Bristle-membraned bodies ('kinetosomes') were also seen to arise from the plasma membrane. We have so far not been able to distinguish these from those elaborated at the nuclear 'pores'. In the literature such have often been referred to as pinocytosis—or absorption—vesicles.

(h) Although we have found no way of distinguishing between the bristle-membraned bodies of differing origin once they have entered the cytoplasm proper, some such bodies in the cytoplasm were observed to be in various stages of condensation into—or synthesis of—denser granules. The most advanced appeared to be in transition from vesicles to ribosome clusters.

(i) Many of the bristle-membraned bodies were seen to be participating in the formation of yolk granules in the oocyte, and vesicles of various sizes were conspicuous among other developing cell organelles, with and without transformation into ribosomes or polyribosomes.

Since we reported the foregoing findings, an electron microscope of higher resolution (Siemens 1A) has been installed in our laboratory and we have examined numerous additional samples of these avian tissues with this more powerful instrument. Thinner sections (400 Å) have been made with a diamond knife mounted on a Porter-Blum MT2 microtome. As was done previously, eggs and embryos were fixed by exposure to 1–2 per cent osmic acid (pH 7.8) for 2 h, were taken up through 50, 75, 95 and 100 per cent ethyl alcohol steps to propylene oxide and were then embedded in 'Epon 812'. Copper grids without support were used and staining with lead was carried out according to method B of Karnofsky⁸.

One of the more gratifying results of this new investigation was the confirmation of something we had suspected earlier, namely, that the bristle-membraned bodies (or 'kinetosome-like' bodies) are largely constituted of small vesicular units of between 150 and 250 Å outside

Fig. 1. Multivesicular body within cytoplasm of 4 mm hen's egg showing outer sheet of vesicles with small internal granules (*g*), membrane (*m*) between outer sheet and inner closely packed sheet of vesicles, 'honey-comb'-like interior with separations composed of small granules or microvesicles and central streak consisting of either granules or microvesicles. A cluster of ribosomes appears to be associated with this body and may be derived from it. ($\times 56,000$)

Fig. 2. Multivesicular bodies from cytoplasm of 1.8 mm hen's egg showing relative sizes of vesicles in shells separated by dense membrane. Note that vesicles of internal sheet also contain very small granules (*g*). ($\times 50,000$)

Fig. 3. Elongated multivesicular body (*nvb*) and ribosome cluster (*rc*) from 6-mm egg. Note that ribosomes are enmeshed in mass of less dense material and are about the same size as larger surface vesicles of multivesicular body (*nvb*). ($\times 120,000$)

Fig. 4. Multivesicular body (*nvb*) with 'tail' which may be condensing into ribosomes (top) and multivesicular body (*nvb*) sectioned through surface sheet of vesicles (bottom). Note dense granules marking centres of vesicles. 6 mm egg ($\times 120,000$)

Fig. 5. Multivesicular body apparently budding off from vesicle (*v*) carrying 'mitochondrion-like' organelle (*mo*) into 6 mm hen's egg. The plasma membrane (*pm*) appears to be homologous to the membrane of the multivesicular body (arrow). ($\times 80,000$)

Fig. 6. Multivesicular body in 6-mm hen's egg with elaborated 'tail'. This suggests that the body may either be (*a*) duplicating itself, (*b*) in an early stage of forming ribosomes or (*c*) both. A section through the surface layer of a multivesicular body is shown (*t*) which clearly reveals the vesicular orientations of this sheet and the central location of the granules. The arrow (insert) points to microvesicles which sometimes appear to comprise the central streaks of these bodies. ($\times 80,000$)

diameter (Figs. 1 and 2). The 'bristles' then, seen at lower resolution, have proved to be the sites at which the sides of adjacent microvesicles are pressed together. It is, however, not clear whether material in addition to that contained in the two membranes may be present at these junctions.

The so-called limiting membrane of the multivesicular body lies between two layers of tightly packed vesicles. In Figs. 1 and 2 it can be seen that the internal layer is made up of somewhat smaller vesicles (about 150 Å) as opposed to those of the external layer (about 200 Å). Figs. 4 and 6 show a cut through the surface layer of one of these bodies and confirm the notion of the regular size and disposition of the microvesicles. Note the presence of small 'granules' in the microvesicles. In Figs. 1 and 2 it can be seen that the 'granules' are present inside the microvesicles of both surface layers. These specks are so small (about 40 Å) that they do not fulfil the

tial requirements for a nucleic acid molecule of any respectable size. At the most they can represent only a nucleotides and, indeed, they might consist of some together different substance. The so-called 'limiting membrane' of the multivesicular body stands out quite distinctly as can be seen in Figs. 1-4. This does not seem to be due to reinforcement due to the pressing together the sides of adjacent microvesicles since, as is seen in Fig. 5 (arrow), the 'limiting membrane' appears to be the usual plasma membrane in those cases where the multivesicular bodies arise from the surface of the cell. The 'limiting membrane' affords a stronger contrast and appears thicker in the vertical regions between the microvesicles and seems somewhat granular. It may be a major site of nucleic acid concentration in these bodies. As we have pointed out before⁶, these bodies display a considerable contrast with the background following destaining with hydrogen peroxide—indicating the presence of a dense material such as nucleic acid. They also stand out in sharp contrast following application of periodic acid and silver methionine as do other nucleic acid-containing structures.

In Figs. 1-3 the impression is obtained that microvesicles organized into somewhat larger wedge-shaped structures 'combed' the interiors of the multivesicular bodies. The dense central streaks in these bodies sometimes appear to be a collection of very small microvesicles (Fig. 6, row). The relative thickness of their walls could account for the dense streak but they may also be condensed into annules.

Conversion of some multivesicular bodies to individual dense objects morphologically indistinguishable from ribosomes and to clusters of ribosomes is strongly suggested by Figs. 7a, b, c and d, and 8. In Fig. 7a several ribosomes are seen extending from a partially condensed, but not the less clearly recognizable, multivesicular body. The 'stalks' appear to consist of very small microvesicles. Fig. 7b shows another such disposition of ribosomes but the multivesicular body is itself beginning to display solid dense nodes. A cut through the surface layer of microvesicles of another multivesicular body (Fig. 7c) shows that many of the microvesicles seem to be filled in with dense material. Three nearly completed ribosome clusters are seen in Fig. 7d. Note that the cluster at the upper right still retains the orientation imposed by the original multivesicular body. In Fig. 8 it appears that entire ribosome clusters may arise from multivesicular bodies without disintegration of these bodies. It is possible that multivesicular bodies even duplicate themselves (body with the long 'tail' in Fig. 6) and these bodies could in turn give rise to ribosomes and ribosome clusters.

Still another piece of evidence for the conversion of multivesicular bodies—or at least cytoplasmic vesicles—into ribosomes is the observation that cytoplasmic

Fig. 8. The connexion between this ribosome cluster (rc) and the multivesicular body (m.v.b.) suggests that one was derived from the other. It seems likely that a 'tail' of more or less organized vesicles was elaborated as in Fig. 6 and that this tail then condensed to give a ribosome cluster. Note vesicular nature of ribosomes and vesicular mass in which they are embedded. ($\times 138,000$)

Fig. 9. Endoplasmic reticulum (er) forming around mitochondria (M) in liver of 6-day-old chicken embryo. Note apparent joining of ribosome-studded vesicles (V). ($\times 25,000$)

Fig. 10. Ribosomes (r) apparently forming from vesiculated surface (arrow) of invaginated pocket of plasma membrane (V) carrying 'mitochondrion-like' organelle into cytoplasm of 6 mm hen's egg. ($\times 42,000$)

Fig. 11. A general darkening in a mitochondrial bud (mb) and the accumulation of vesicles (v) are associated with the maturation and increase in size of a mitochondrion in somatic tissue of a 1-day-old chicken embryo. ($\times 26,000$)

vesicles in embryonic cells sometimes appear to fuse or elaborate into endoplasmic reticulum. This characteristically occurs at a more-or-less regular distance from a newly developed mitochondrion. Not only is the resulting endoplasmic reticulum studded with ribosomes but dense granules sometimes appear in the migrating vesicles prior to complete incorporation into the reticular system (Fig. 9).

For a time we thought that multivesicular bodies arising from the plasma membrane, although thus far morphologically indistinguishable from such bodies elaborated from the nuclear pores, might not display the apparent capacity for producing ribosomes¹⁵. However, further investigations in the oocyte have revealed that the plasma membrane often is converted in localized regions into a layer (or layers) of microvesicles (Figs. 5 and 10). It is from these regions that the multivesicular bodies of plasma membrane origin appear to be elaborated inward into the cytoplasm. As can be seen in Fig. 10, individual ribosomes are sometimes connected to the vesicular surface of the plasma membrane by thin, probably vesicular, strands. Because of the similarity of this orientation to that observed in those multivesicular bodies undergoing the first stages of differentiation into ribosome clusters (Fig. 7a), we entertain the possibilities: (a) that they may be elaborated from materials within the plasma membrane or (b) synthesized under the direction of—or in association with—this vesicular membrane.

We have no unequivocal proof that the multivesicular bodies specifically arising from the nuclear pores also give rise to ribosomes and ribosome clusters. However, incompletely developed ribosome clusters have been seen associated with nuclear forces. Moreover, in view of our theory that nucleolar nucleic acid is exported from the nucleus to the cytoplasm in this physical form and from the evidence presented by Edström⁹ that nucleolar RNA has

Fig. 7 a, b, c, d. This sequence suggests one mode of evolution of ribosomes and ribosome clusters from multivesicular bodies. ($\times 46,000$)

a similar base ratio to ribosomal RNA, this seems likely. Also, the extreme similarity in morphology between multivesicular bodies arising from nucleus and plasma membrane suggests the existence of this degree of similarity of function.

It is, to say the least, challenging to attempt correlation of the foregoing observations with recently proposed schemes for nucleic acid participation in protein synthesis by Gierer¹, Noll *et al.*² and Rich *et al.*³, in which the individual ribosomes are considered as single manufacturing units transcribing information for amino-acid sequence by movement from one end of an mRNA strand to the other. The nature of the evolution of the ribosome clusters in avian material suggests that the connexions from one ribosome to the other is derived from material originally present in the multivesicular precursor or at least from materials elaborated *in situ*. Although this connecting material may be mRNA already incorporated into the multivesicular body, the presence of as many as 20 ribosomes in such a cluster, the apparent linking of many ribosomes in more than two directions (indeed, by a mass of material in some cases, Figs. 3 and 8) and the presence of a centrally located ribosome in the cluster as well as encapsulating membrane material in some cases (Figs. 3 and 8), would seem to preclude the possibility of this unit acting in the manner proposed by the foregoing authors, namely, the simple movement of ribosomes in a single direction along a strand of mRNA.

Perhaps the ribosome clusters as such are not actively participating in protein synthesis. We have seen many examples in which individual ribosomes are attached by the thinnest of threads to the main mass of a multivesicular body. These may detach from the main body and thus become available to associate with a strand of messenger RNA forming a 'true' polyribosome. Following an essentially similar principle the entire ribosome clusters might disintegrate, again releasing individual ribosomes.

On the other hand, the ribosome-mRNA read-off-concept is difficult to apply to protein synthesis as it takes place in the plasma membrane, in growing mitochondria (Fig. 11) and in endoplasmic reticulum. Few, if any, such classical orientations of ribosomes and mRNA can be seen in these structures although it might be assumed that the ribosomes on the outside surface of the endoplasmic reticulum are reading off a code from mRNA in, or applied to, the membrane. Nisman and Pelmont⁵ have pointed out that careful analysis of several systems forces the conclusion that a complete *de novo* synthesis of protein does not occur in material lacking membrane or lipoprotein and that ribosomes are usually associated with such systems. Henshaw *et al.*¹⁰ have demonstrated that the major active unit for amino-acid incorporation in microsomal materials is, however, much larger than a ribosome cluster. In the livers of roosters that have received pharmacodynamic doses of oestrogens and are consequently synthesizing large amounts of phosphoproteins, we see relatively few ribosome clusters but many more ribosomes associated with a hypertrophied endoplasmic reticulum.

The apparent participation of multivesicular bodies and smaller vesicular structures which may be derivatives of multivesicular bodies in formation of yolk granules, Golgi complex, mitochondria and plasma membrane⁶ as well as cilia⁷, implies that guidance of protein incorporation into definite structure (and, probably, synthesis of protein) can be accomplished by some property of certain vesicular bodies and does not directly require the presence of ribosomes. Messenger RNA may already be present in multivesicular bodies or may associate with them in the cytoplasm and consequently may also be present in or about the structures into which the vesicles are incorporated. In these circumstances, the mRNA may be transcribed by some process other than the movement of granular ribosomes. Beljanski *et al.*¹¹ have demonstrated

the presence of an RNA in *Alcaligenes faecalis*, which accepts amino-acids directly in a ratio of one amino-acid per 6 nucleotides. Existence of DNA as well as RNA has been demonstrated in plasma membrane¹² mitochondria and *E. coli* spheroplast membranes⁵. Labelling with actinomycin D has revealed the presence in the cytoplasm of developing frog's eggs of considerable amounts of DNA largely contributed from the surrounding follicular cells. These findings, taken together with the foregoing observations, lead to the conclusion that although a variety of protein-synthesizing mechanisms may obtain in the same cell, multivesicular bodies, the ultimate origins of which would be expected to be nuclear, either that existing in the present cell, one contained in a contributing cell, one which existed in a relatively close ancestor, may of paramount importance. By means of such bodily elements necessary for protein synthesis, disbursement both, may possibly be sent, stored, duplicated, transcribed into structure and, perhaps, often re-transcribed in such mobile units, according to the demands of the immediate environment.

Balbani Ring Particles in the Cytoplasm?

In the cytoplasm of oocytes which have attained size of about 1.5–2.0 mm but not in eggs larger than 4 mm diameter, we have consistently observed the presence of largish (about 300 Å) particles. These occur singly

Fig. 12. The 300-Å particles (*p*) seen in the cytoplasm (*C*) of this 2-mm egg appear to have emerged from the nuclear pores (*P*) (see arrows for 2 examples), but the particles usually observed in the centres of these pores are always smaller (see tangential cuts through such pores in insert). The size, appearance and apparent origin of the larger particles suggest that they may be Balbani ring granules containing messenger RNA. *r* = ribosomes. *N* = nucleus. ($\times 50,000$)

Fig. 13. These two examples of 300-Å particles apparently having just passed through the nuclear pores (arrows) indicate either that the particles re-form from several smaller particles after entering the cytoplasm or that they sometimes unravel in the cytoplasm. It will be noted that even in the condensed form they appear to consist of several dense subunits. The insert shows the relative size of ribosomes, here arranged in a cluster. ($\times 50,000$)

Fig. 14. A presumed Balbani ring granule (*G*) is depicted here, apparently in the process of entering an annular, or nuclear, pore. *NM* = nuclear membrane. *CM* = cytoplasmic membrane. ($\times 55,000$)

Fig. 15. Many such 300-Å particles (enclosed in a matrix or membrane sheath, arrow) are seen in the intercellular spaces (*S*) between follicular cells at the time of rapid synthesis of 'mitochondrion-like' organelles (*mo*) by these cells. ($\times 50,000$)

most part and appear to be slightly more dense in their centres and along their peripheries (Figs. 12 and 13). In some cases they appear to be condensed into several nested sub-granules. Although detectable in the cytoplasm, they are present there in much less concentration than in the cytoplasm, a situation which may be due to relatively poor fixation of the interior of the nucleus. In many cases (Figs. 12 and 13) they are associated with the nuclear pores that they give the impression of having emerged from these. In Fig. 14 similarly sized particles are observed on the nuclear side of the nuclear pores. Although it is possible (perhaps even probable) that they are essentially identical with the granules observed to be present in most of the apertures of the pores (Fig. 12, insert), few instances have been seen in which the granules in the pores are as large as the large such particles in the cytoplasm. Perhaps, as is suggested in Fig. 13 (arrows) an at least partial unravelling of the granule occurs during passage through an annular pore. In morphological appearance, mode of distribution and size, these granules closely resemble the particles that originate at the sites of the Balbiani puffs, or rings, on chromosomes¹⁴. Because of the site of their origin and base ratios of the RNA associated with the Balbiani puffs⁹ the so-called Balbiani ring particles are thought to consist largely of messenger RNA. Thus, the observed particles in the cytoplasm of oocytes of this stage may represent messenger RNA.

If these particles are indeed Balbiani ring particles, as may be the first observed instance of such bodies appearing in compact form in cytoplasm. Beermann and others have shown them in the process of passing through the nuclear 'pores' of giant cells in Diptera, but in this case they appear to assume a more dispersed or thread-like form immediately on entry into the cytoplasm¹⁴.

As mentioned earlier, we have seen these granules in the cytoplasm of the oocyte at only one stage of maturation (1.5–4.0 mm egg size). It is possible that they are en route to cytoplasmic or plasma membrane sites where they can be incorporated for future utilization. On the other hand, they may be participating in some function that is peculiar to, or being originated at, this stage of development. A most conspicuous such process is the formation of 'mitochondrion-like' organelles¹⁶. Although these are synthesized at the surfaces of the follicular cells, it is suspected that the 'messages' for such syntheses originate in the oocyte. Their ultimate destinations are, indeed, the yolk granules of the developing egg. We have

long been puzzled by the occasional presence of dense granules (about 300 Å) enclosed in what appear to be envelopes of plasma membrane, in the intercellular spaces (Fig. 15). Is it possible that these granules are Balbiani ring particles carrying information to the surfaces of the follicular cells from the oocyte?

If this be so, a logical explanation is forthcoming for the occurrence of Balbiani ring granules in a condensed form (resistant to RNases) in the cytoplasm of the small oocyte. The condensed form of the messenger might provide an efficient 'capsule' for the transport of information through a region where not only is it not required but where it might also be detrimental. Inherent in this concept is the principle that condensed mRNA is recognized by, or recognizes, the site where it is to unfold and carry out its function.

¹⁵ Roth, T. F., and Porter, K. E., *Fifth Intern. Cong. Electron Microscopy* (1962), suggest that the movement of multivesicular bodies (their 'specialized sites on the cell surface for protein uptake') from the cell surface to the developing yolk granules constitutes circumstantial evidence that this is the form in which yolk proteins are carried from the circulation to the yolk granule. In this connexion we have noted that the surface sheet of vesicles of the multivesicular body are usually stripped off before this body joins the yolk granule. However, the vesicular nature of the internal sheet and the centrally located granules (Figs. 1, 2) suggest that at least this layer is also not made up of yolk proteins. It is possible that a major function of the stripped multivesicular bodies is to provide nucleic acids to the yolk granules (these are known to be present therein) but this question (and the question of yolk protein transport by these bodies) is yet to be resolved.

BREAKDOWN RATE OF SERUM 7S γ -GLOBULINS IN MICE

By DR. D. E. H. TEE, DR. J. WATKINS and MILDRED WANG

Department of Pathology, King's College Hospital Medical School, London, S.E.5

THE turnover rate of γ -globulin has been determined in a number of animal species by means of radioisotopically labelled protein. The rate of γ -globulin catabolism can be influenced by several factors. An investigation by Fahey *et al.*¹ on mice indicates that these factors include the metabolic rate of host, specific features of the protein molecule, the serum γ -globulin level and, indirectly, the rate of synthesis of γ -globulin. The production of antibodies might also be expected to confer a different catabolic rate on the γ -globulin fraction containing the antibody.

Preliminary work has shown that the antibody response in mice to hyperimmunization with homologous transplantable tumours is confined to the 7S γ -globulin fraction². Ultracentrifuge investigations have revealed appreciable increases in molecular heterogeneity of 7S

γ -globulin samples isolated from mice immunized with homologous transplantable tumours, as compared with 7S γ -globulin samples from non-immunized mice of the same strain³.

In view of the wide range of electrophoretic mobilities of 7S γ -globulin of mice and other species, it is difficult to believe that all the 7S γ -globulin molecules arise from the same site or are broken down in an identical fashion. It is therefore of interest to know whether there are differences in the breakdown rates of normal and hyperimmune serum 7S γ -globulins and whether fractions of these 7S γ -globulins, with different mean electrophoretic mobility on starch gel, also show differences.

Four series of experiments were carried out and details of strain and sex of the mice are tabulated in Table 1. Batches of about 50 normal mice of each strain were bled

Table 1. MEAN BIOLOGICAL HALF-LIFE VALUES OF MOUSE SERUM γ -GLOBULINS AS DETERMINED BY DIFFERENT METHODS

Exp. No.	Strain	Sex	No. of mice	Body count method	Serum method	Starch-gel method
Normal mice						
1	Albino	M	6	—	4.6 ± 0.37	4.4 ± 0.29
2	Albino	F	6	4.5 ± 0.16	4.3 ± 0.15	4.2 ± 0.17
3	129	3 M, 3 F	6	4.4 ± 0.29	—	3.9 ± 0.25
Immune mice						
4	129	4 M, 4 F	8	5.0 ± 0.21	5.6 ± 0.35	5.1 ± 0.23

from the tail vein to provide normal sera. Immune serum was obtained from a batch of 50 mice 129 strain immunized with a transplantable mouse sarcoma BP8. The immunizing tumour BP8 was kindly supplied by Dr. J. R. Batchelor, of Guy's Hospital Medical School, London, and this was maintained in this laboratory in strain C57BL mice. The mice received three subcutaneous injections over a period of about 3 months of the freshly homogenized tumour, collected from the C57BL mice. The sera of these mice showed considerable agglutinating activity against C57BL red cells at the end of this period.

7S γ -globulin was isolated from the normal and the immune sera by chromatography on Whatman DEAE-cellulose³. These preparations appeared to be free from other serum proteins as shown by starch gel-electrophoresis, immunoelectrophoresis (using rabbit anti-mouse serum antiserum) and by sedimentation velocity analysis³. Autoradiography after immunoelectrophoresis of preparations labelled with iodine-131 revealed some contamination with β -globulin. However, only labelled γ -globulin could be detected by this technique in serum taken from the mice 5 days after injection of the labelled γ -globulin.

The γ -globulin preparations (10 mg/ml.) were labelled with iodine-131 according to the method of McFarlane⁴, without preoxidation, and diluted with isologous mouse serum to produce solutions with activities of 100–200 μ c./ml. 0.2–0.5 ml. of these solutions were injected intraperitoneally into normal mice of the isologous strain. Before and during the experiment, the mice were given drinking-water containing sodium iodide. The total amount of γ -globulin, labelled and unlabelled, injected into each mouse was of the order 2–10 mg. This additional γ -globulin would not be expected to have any significant effect on the rate of γ -globulin catabolism.

Radiation counts were made using an annular sample arrangement with a 15-mm cylindrical sodium iodide crystal and a Panax 'Dekatron' scaler type D 657. C. The total decay of the labelled protein was followed in three ways. These were: (a) total-body counts; (b) serum counts; (c) counts of the γ -globulin fraction of the serum after separation by starch-gel electrophoresis. The latter is referred to as the starch-gel method in this article.

For method (a) each mouse was lightly anaesthetized with ether and introduced into a Paxolin tube symmetrically situated between four integrated Geiger-Müller probes. For methods (b) and (c) 0.2 ml. of blood was obtained from each mouse by bleeding from the tail vein⁵ at suitable intervals of time. Serum from each mouse was separated individually and 0.02 ml. volumes were diluted with 10 ml. normal saline for counting. Further 0.02 ml. serum samples were electrophoresed on starch gel. After electrophoresis the starch gel was sliced horizontally and both halves stained with amido black. Two fractions of the γ -globulin zone were cut out from each half of the gel. One fraction, designated S_{γ} , was cut out between the loading origin on the gel and the stained $S\alpha_2$ globulin band. The other fraction, designated F_{γ} , was the remainder of the γ -globulin up to, but excluding, the β -globulin bands. Measurements showed that the radioactivity was almost exclusively confined to the stained γ -globulin zone. Not more than 1 per cent of the overall activity was associated with the β -globulin bands and some of this was probably due to γ -globulin contamination. The gel fractions were each dissolved in 10 ml. N sodium hydroxide and counted.

Fig. 1. Biological half-life values of the serum 7S γ -globulins of individual mice as determined by different methods. ●, Normal mice; ○, immune mice; —, mean values of half-life for normal mice; —, mean values of half-life for immune mice

The radioactivity counts obtained by each method were corrected for normal isotopic decay. Activity measurements were made 4 or 5 days after injection of the dose and were continued for up to 22 days. Biological half-life values were computed graphically for individual mice from plots of \log_{10} radioactivity against time. These half-life values were averaged and the standard error evaluated for each experiment and for each method (Table 1). The individual values are shown in Fig. 1.

These experiments suggested that there was no difference in the rate of γ -globulin turnover between the two sexes. In order to verify this, 15 male and 15 female mice strain 129 were injected with labelled normal γ -globulin and the rate of breakdown followed by the body-count method. Average half-life values of 4.6 ± 0.11 and 4.9 ± 0.17 days were obtained respectively for male and female mice. The difference between these values is not statistically significant.

The values calculated from body and serum counts were in close agreement with the starch-gel values. The starch-gel method provided three half-life values for γ -globulin, corresponding to the turnover rates of the total 7S γ -globulin (T_{γ}), and S_{γ} and the F_{γ} fractions. Table 2 shows the average half-life values obtained by the starch-gel method. The difference in rate of turnover between the S_{γ} and F_{γ} globulin fractions of normal γ -globulin was statistically highly significant.

In normal iodine-131-labelled γ -globulin preparation the initial ratio of the radioactivity in the two fractions expressed as S_{γ}/F_{γ} , was about 1.5–2. However, with labelled immune preparations, produced from two different strains of mice immunized with different transplantable tumours, ratios of about 6–8 were observed. Similar relative increases in concentration of a slow electrophoretic fraction of the γ -globulin have been observed semi-quantitatively in the immune response of the mouse to other antigens, and agglutinating antibody was largely confined to this slow fraction⁶. The extremely low level of radioactivity associated with the F_{γ} fraction of the immune γ -globulin preparation made it difficult experimentally to obtain a value of the half-life of this fraction with any degree of accuracy.

Table 2. MEAN BIOLOGICAL HALF-LIFE VALUES OF NORMAL MOUSE SERUM 7S γ -GLOBULIN FRACTIONS

	Half-life (days)
Total 7S γ -globulin (T_{γ})	4.2 ± 0.12
Slow fraction (S_{γ})	3.6 ± 0.14
Fast fraction (F_{γ})	4.6 ± 0.16

The immune γ -globulin preparation had a longer half-life in normal mice than the corresponding normal globulin preparation. This difference was highly significant statistically. This effect might have been produced by the presence of long-lived impurities in the immune preparations which were absent in the normal preparation. Similar consideration could, of course, apply to the α and $F\gamma$ fractions. There was no evidence, however, to indicate that the immune γ -globulin was significantly less pure than the normal γ -globulin. Since β -globulins had not been detected as minor impurities in both preparations by autoradiography, it was possible that the differences in catabolism rate might be correlated with small differences in the level of this impurity. Mouse β -globulins were separated from serum using DEAE-'Sephadex' chromatography. Preliminary experiments showed that the rate of turnover of β -globulin in the normal mouse was very similar to that of 7S γ -globulin, indicating that β -globulins are not responsible for any of the observed differences. It was found necessary to use freshly isolated γ -globulins from fresh sera or sera stored at -20°C for only a short time. γ -Globulin isolated from serum which had been stored at -20°C for 18 months behaved normally in starch-gel electrophoresis, immunoelectrophoresis and sedimentation velocity analysis. However, when labelled and re-introduced into mice, it was found to have a half-life of only two days. The fact that the decay of this globulin was constant for some 20 days shows that this is not denatured protein in the usual sense. It seems probable that this γ -globulin had undergone some degree of limited aggregation. Such aggregation phenomena in purified γ -globulin preparations have been reported by other workers^{8,9}. Limited aggregation of the molecules, *in vivo* or *in vitro*, may be responsible for the observed differences between the $S\gamma$ and $F\gamma$ fractions.

In summary, these studies indicate a mean biological half-life of about 4.2 days for normal mouse γ -globulin. The turnover rate did not appear to be influenced by either the sex or the strain of the mouse. The use of starch-gel electrophoresis for separating the labelled γ -globulin has made it possible to examine the rates of turnover of two fractions of the γ -globulin. These fractions, corresponding to molecules migrating with different mean mobilities when electrophoresed, had mean half-lives of 3.6 days ($S\gamma$) and 4.6 days ($F\gamma$) respectively. The fractions are probably identical with those identified by Fahey on the basis of immunological differences and on their electrophoretic mobility on starch-gel.

Immunization of 129-strain mice with transplantable tumour type BP8 produced hyperimmune γ -globulin which had a longer half-life than the corresponding normal γ -globulin preparation when re-introduced into normal 129-strain mice. The reasons for this are unknown, but it appears that this effect is not produced by long-lived impurities in the immune γ -globulin preparation. The considerable increase in the radioactivity ratio, $S\gamma/F\gamma$, of immune γ -globulins as compared with normal γ -globulins may indicate a specific response to immunization in some fraction of the 7S γ -globulin and not in the 7S γ -globulin as a whole.

LABELLING OF MOUSE THYMOCYTES *IN VIVO* WITH TRITIATED THYMIDINE FOR CELL TRANSFER EXPERIMENTS

By DR. KIRSTINE BORUM*

National Bacteriological Laboratory, Stockholm, Sweden

N experiments designed for the tracing of tritiated thymidine-labelled donor thymocytes after injection to a recipient animal it is of importance that the donor cell suspension should have a high percentage of labelled cells. In autoradiographic detection of transfused cells, reasonably high grain count per cell is also desirable.

After a single injection of tritiated thymidine 15–20 per cent¹ and 6.1 per cent² of mouse thymocytes are reported to have been labelled, and 7–17 per cent³ of guinea-pig thymocytes.

In vitro culturing of thymocytes in a medium containing tritiated thymidine has also been applied. With this method 9 per cent of rat thymocytes⁴, 6.8 per cent⁵ and 7–12 per cent⁶ of guinea-pig thymocytes, and 6.7 per cent of mouse thymocytes⁷ were found to be labelled.

Repeated injections of tritiated thymidine *in vivo* have given a higher yield of labelled cells in the thymus. Everett *et al.*⁸, in rats, obtained a proportion of labelled thymocytes of 50 per cent after injections every 4 h for 6 h, and Murray *et al.*⁷ report a proportion of 50 per cent after three intraperitoneal injections. In young mice Sims⁹ found a maximum count of 54 per cent after six injections every fifth hour.

In the present study, inbred CBA male mice were used. Tritiated thymidine (Schwarz) with a specific

activity of 3 c./mmole was diluted in nine volumes of sterile saline to a concentration of 0.1 mc./ml., and 1 or 2 $\mu\text{c.}$ per g body-weight was injected intraperitoneally at 12 h intervals (Table 1).

From $\frac{1}{2}$ to $3\frac{1}{2}$ h after the last thymidine injection the mice were killed in ether and the thymuses removed immediately. One half the organ was fixed in 4 per cent neutral buffered formal and embedded in paraffin. Histological sections were Feulgen stained and, after being thoroughly rinsed in distilled water, were coated with 'NTB₂' (Kodak) photographic emulsion in the dark room. Autoradiographs were exposed at 4°C for five weeks and developed, fixed and rinsed in tap water for half an hour, and thereafter in distilled water. The other

* Present address: Department of Rheumatology, University Hospital, Lund, Sweden.

half of the thymus was made into a cell suspension. The organ was cut with fine scissors and gently pressed through a stainless-steel mesh into a small volume of Tyrode's solution. For the preparation of smears one part of the cell suspension was mixed with an equal volume of normal mouse serum. A small drop of this mixture was placed on a glass slide which immediately before had been smeared with a solution of 20 per cent mouse serum in 0.25 M sucrose. As the sample of the cell suspension came into contact with the still moist area on the glass slide, it would spread evenly when the slide was tilted slowly. It is believed that this technique for making smears will cause little damage to fragile cells. After drying in cool air, the smears were fixed in absolute methanol for one hour and prepared for autoradiography as described above for the sections. After processing, rinsing and drying, the smears were stained through the 'NTB₃' film with Giemsa stain by the method of Gude *et al.*⁹ (Fig. 3). The percentage of labelled cells was determined by counting 1,000 cells. A density of four grains over a cell area corresponding to that of a small lymphocyte was considered as significant labelling. The labelling percentages will be seen in Table 1.

The size of the thymus in the donor animal is also of some importance in the preparation of labelled thymocyte suspensions. To study the changes in size with age, male and female mice were killed at intervals from the day of birth to the age of one year and their thymuses weighed. In male *CBA* mice, the thymus reaches its greatest weight at the age from 20 to 30 days, in the females at the age from 25 to 35 days. The weight of the thymus in relation to body-weight as a function of age

Fig. 1. Weight of thymus in relation to body-weight for male and female mice as a function of age. Each column represents the mean of values from several animals with ages within the interval indicated: days 10-14 from seven mice, days 15-19 from seven mice, days 20-24 from four mice, and days 25-29 from four mice. The single lines represent values for one or the average of two mice from the same day.

Fig. 2. Autoradiograph of Feulgen-stained section of mouse thymus. The mouse was, at the age of seven weeks, given seven injections of tritiated thymidine intraperitoneally at 12-h intervals. Virtually all cells in the thymic cortex are labelled. ($\times 250$)

Fig. 3. Autoradiograph of Giemsa-stained smear of a thymus cell suspension. From the eleventh to the fifteenth day of age the mice received eight intraperitoneal injections of tritiated thymidine. All cells except a small lymphocyte carry label. ($\times 1,000$)

is shown in Fig. 1. It appears that the relative size reaches a maximum between 10 and 15 days of age in male mice and between 15 and 20 days of age in female mice. As the highest labelling percentage in our study 88 per cent, was also obtained at the age interval from 11 to 15 days in the males, this age seems most favourable from the point of view of isotope economy in labelling the thymus with tritiated thymidine for the purpose of making cell suspensions.

The high labelling percentage after several injections of tritiated thymidine every twelfth hour is due to the fact that virtually all cells in the thymic cortex carry the label (Fig. 2). In the not so densely populated thymi

hulla the labelled cells are scarce. From autoradiographic studies of cellular kinetics in mouse thymus¹⁰ there is evidence showing that the population of lymphocytes in the thymic cortex is renewed every fourth day. Therefore, for purposes of labelling it seems to be less to continue injections of tritiated thymidine for more than four days because of the continuous loss of label from the thymus, probably due to emigration of small thymocytes. Augmenting the dose of tritiated thymidine from 1 to 2 μ c. per g body-weight appears to give a higher labelling percentage. It is for the investigator to decide whether the possible radiation damage from the higher dose will be acceptable in his experimental set-up.

Preliminary results from experiments where the donor lymphocyte suspension pooled from mice Nos. 7-9 was injected intraperitoneally into isologous mice showed that at 1 and 4 days after the injection labelled lymphocytes

were found in the spleen and lymph-nodes, and more diffuse labelling was noted in the liver. No labelling was detected in the thymus.

This study was supported by a grant from the Swedish Medical Research Council, project F-0143-B-A.

EFFECT OF A PYRIMIDOPYRIMIDINE DERIVATIVE ON THROMBUS FORMATION IN THE RABBIT

By DR. P. R. EMMONS, M. J. G. HARRISON, DR. A. J. HONOUR and DR. J. R. A. MITCHELL

Department of the Regius Professor of Medicine, Radcliffe Infirmary, Oxford

BORN, Honour and Mitchell¹ showed that the systemic administration of adenosine and 2-chloradenosine modified the behaviour of platelet thrombi in injured arteries in the rabbit. They suggested that if these substances proved to be free from toxic effects, they might be of value in the prevention and treatment of human arterial thrombosis. Adenosine is a powerful vasodilator², and produces a marked fall in arterial blood-pressure; moreover, it is rapidly broken down in the body by deamination. 2-Chloradenosine is more resistant to deamination³, but produced respiratory arrest in two of the rabbits examined by Born, Honour and Mitchell¹. When unag *et al.*⁴ reported that a pyrimidopyrimidine derivative (RA8-Persantin; Boehringer-Ingelheim, Ltd.) retarded the rate of disappearance of exogenous adenosine from whole blood *in vitro*, it seemed possible that this compound might be used to potentiate exogenous adenosine *in vivo*, and permit the anti-thrombotic effect observed by Born, Honour and Mitchell¹ to be obtained with lower doses. A detailed examination of the properties of the compound was therefore undertaken⁵. In concentrations of 10^{-4} M, RA8 was found to inhibit the platelet aggregation produced *in vitro* by adenosine diphosphate (ADP); no exogenous adenosine had to be added to produce this effect. It therefore seemed profitable to examine the effects of RA8 on thrombus formation *in vivo*, and this article reports the results of these observations.

Grey chinchilla rabbits of either sex (2.9-4.6 kg) were used. Each rabbit was anaesthetized with urethane (6.0 ml. per kg of a 25 percent solution in 0.9 percent sodium chloride injected intraperitoneally) and a tracheotomy tube was inserted. Arterial blood-pressure was recorded kymographically from a cannula in the femoral artery and intravenous injections were given through a polythene cannula tied into the left external jugular vein, the catheter being perfused with normal saline at a rate of 0.1 ml./min between injections. Blood samples for platelet clumping were withdrawn from a polythene cannula passed down the left common carotid artery into the aorta. Between samples the cannula was occluded with a wire stilette, and the samples were collected into all-glass syringes, lubricated with silicone fluid (MS 550; Hopkin and Williams). Platelet-rich citrated plasma was then prepared, and its clumping activity was determined by the Born

optical density method⁶, the details of the techniques used being set out fully elsewhere⁷.

The right cerebral cortex was exposed and the vessels on its surface observed as described by Honour and Ross Russell⁸. Two degrees of arterial injury⁹ were used to assess the effects of RA8.

(a) *Major injury.* An artery was pinched firmly with needle-pointed ophthalmic forceps, causing bleeding and the formation of a haemostatic plug outside the vessel. Inside the vessel a steady succession of white platelet masses or 'white bodies' formed at the site of injury and embolized. By observing the size of the emboli and by timing their rate and duration of production, the activity of the site could be assessed.

(b) *Minor injury.* An artery was gripped gently with the forceps. This did not produce bleeding and no white bodies formed spontaneously. When solutions of ADP, adenosine triphosphate (ATP) or 5-hydroxytryptamine were applied to the external surface of the injury, platelet masses formed in the lumen and embolized for as long as the application was continued. By applying the agents in a standard way (1 drop/sec for 1 min) and by testing progressively lower concentrations, the lowest concentration of each agent which produced white bodies was determined.

(A) *RA8 given after major injury.* Table 1 summarizes the results obtained in 7 rabbits which were given a single intravenous injection of RA8. In each case, a major injury had been inflicted at least 30 min before the injection, and the steady production of white bodies had been

Table 1. EFFECT OF INTRAVENOUS INJECTIONS OF RA8 ON THE PRODUCTION AND EMBOLIZATION OF WHITE BODIES AT MAJOR INJURY SITES

Rabbit	RA8 dose (mg)(mg/kg)	Effect	Interval from injection to effect (min)	Duration of effect
I	40 10.3	White body formation stopped	1	Still present at 5 h
II	10 3.0	" "	9	Present at 4 h
III	10 2.7	" "	2	Present at 3 h
IV	10 2.4	" "	3	Present at 3 h
V	5 1.5	" "	10	Present at 3 h
VI	1 0.3	Small, fragmentary white bodies formed, which washed away as they developed	8	20 min, but masses still abnormal at 4 h
VII	0.25 0.06	Small white bodies which did not stick at bifurcations	5	11 min

observed and timed. When more than 1.5 mg/kg of RA8 was given, white body formation was completely abolished, and did not start again during a prolonged period of observation. In these rabbits, a qualitative change in the character of the white bodies was noted in the interval between the injection of RA8 and the cessation of activity: the masses became smaller, were pink, floccular and less well defined. They streamed away rapidly from the site and did not become impacted at bifurcations. These changes were similar to those observed by Born *et al.*¹ when adenosine and 2-chloradenosine were given. The lower doses (rabbits VI and VII) did not abolish white body production, but profoundly modified the activity of the site. The white bodies produced were very small, in comparison with those seen in the control period, and for a period of 20 min and 11 min respectively in these two rabbits, the platelet masses consisted merely of swirling fragments which did not stick at bifurcations.

(B) *Behaviour of major injuries inflicted after RA8 injections.* Major injuries were inflicted on two rabbits, and observed for 15 min, during which period a steady succession of dense white bodies formed and embolized. When these masses left the injury site they stuck at bifurcations. Each rabbit was given 10 mg RA8 intravenously and in 2 and 3 min respectively the initial injury sites were inactive. Major injuries were then inflicted at intervals after the RA8 injection, new arterial systems being used for each injury. Table 2 shows that the duration of white body formation at each new injury site increased with the passage of time after RA8 administration. The nature of the masses produced also showed a graded response with time: injuries inflicted immediately after RA8 could only produce a faint hazy mass, while at longer intervals after the injection the masses became larger, more persistent and more dense. None of the injuries produced an unusual amount of bleeding, and firm external haemostatic plugs formed on the outside of the injured vessels in the usual way. Even the injuries inflicted immediately after the RA8 had been given showed a normal haemostatic response, although these sites could only produce feeble, transient white bodies. Born *et al.*¹ found a similar dissociation between haemostasis and thrombosis when adenosine and 2-chloradenosine were given, and this holds out the hope that effective antithrombotic drugs may be found which do not prejudice haemostasis. The dissociation between external and internal platelet plug formation may mean that the stimulus to platelet aggregation in blood shed from a vessel is different from the mechanism which operates within the lumen, or that the mechanism is the same, but that the initial response of the injury site is so intense that it cannot be blocked by any of the agents so far tested.

(C) *Effect of RA8 on minor injuries.* Table 3 shows the effect of RA8, 10 mg given intravenously, on the lowest concentrations of the three clumping agents which were able to produce white bodies when they were applied to a minor injury site. Eighteen min after RA8 had been given, the response to 5HT had been abolished, while the end-point levels for ADP and ATP had only changed by a factor of two and four respectively. However, the character of the ADP and ATP response had been profoundly changed. Under control conditions, increasing the concentration of the locally applied substances above the

Table 3. EFFECT OF INTRAVENOUS RA8 (10 MG, 2.6 MG/KG) ON THE MIN EFFECTIVE CONCENTRATIONS OF ADP, ATP AND 5HT WHICH WERE CAPABLE OF PRODUCING WHITE BODIES AT A MINOR INJURY SITE

Substance	Before RA8	Minimal effective concentration (μg/ml.)		
		18 min after RA8	At 30-min intervals after RA8	5 h after RA8
ADP	8	16	Not tested	8
ATP	2	8	Not tested	2
5HT	2	No effect from 250	No effect from 250	No effect from 250

Table 4. EFFECT OF A SERIES OF INJECTIONS OF RA8 ON THE MIN CONCENTRATION OF 5HT WHICH WAS CAPABLE OF PRODUCING WHITE BODIES AT A MINOR INJURY SITE

(mg)	RA8 dose (mg/kg)	Minimal effective concentration of 5HT (μg at specified intervals after RA8 injection)			
		0	0.5	0.5	0.5
0.25	0.09	+6 min	2.0	+60 min	2.0
0.5	0.17	+3 min	8.0	+37 min	8.0
1.0	0.34	+2 min	64.0	+60 min	4.0

end-point produces progressively larger, denser and more persistent bodies; after RA8 this graded response was lost and ADP and ATP at concentrations of up to 250 μg/ml. produced the same faint, transient masses which the end-point concentrations evoked. 5 h after the RA8 injection the site still did not respond to 5HT, 250 μg/ml., where it had regained its responsiveness to ADP and ATP. The end-points having returned to their pre-RA8 level and the normal gradation of response being restored.

Table 4 shows that the effect of RA8 on the 5HT sensitivity of a minor injury site is closely related to the dose used, 0.25 mg giving a four-fold decrease in sensitivity, 0.5 mg a sixteen-fold reduction and 1.0 mg reducing it a factor of 1/128. In rabbit X (Table 3), which received 10 mg RA8, the change in 5HT response persisted more than 5 h, whereas in rabbit XI, which received or 1.75 mg, spread over 97 min, the 5HT responsiveness was beginning to return some 60 min after the last RA8 injection.

(D) *Effect of local application of RA8.* A major injury was inflicted, and was observed to produce dense, adherent white bodies for 23 min. RA8, 500 μg/ml. in physiological saline, was then applied to the external surface of the injury at 1 ml./min for 5 min. As soon as the application began, the white bodies became smaller (only grew half-way across the lumen before embolizing, where they had previously been filling the whole lumen) and were less dense, appearing to wash away as rapidly as they were forming. Twenty-one min after the beginning of the application, the site became inactive and did not regain its activity in a 200-min period of observation. 107 min after the application, the responsiveness of the site to ADP, ATP and 5HT was tested. ADP and ATP both produced characteristic white bodies (end-point 2 μg/ml. for each agent with a normal gradation of response to higher concentrations) while 32 μg/ml. of 5HT was needed for white body production. Higher concentrations of 5HT produced white bodies similar in size, density and duration to those seen with the end-point concentration. A second major injury was then inflicted, and after it had produced white bodies for 15 min, RA8, 500 μg/ml., was applied as already described here. Once again, there was immediate reduction in the size of the white bodies, and 20 min after the application, the site became inactive.

A major injury was inflicted on another rabbit. The site produced huge, tenacious white masses for 26 min. RA8, 100 μg/ml. in saline, was then applied, and within 1 min the white mass present at the site began to break up and wash away. Small, fragmentary white bodies continued to form, but 37 min after the start of the application the site became quiescent and remained so for the remaining 2 h in which the preparation was observed.

(E) *Effect of RA8 on circulating platelets.* The inhibitory effect of RA8 applied locally to injured arteries shows that the agent can act directly on the injury site, but in view of the reduction of *in vitro* platelet clumping activity observed by Emmons *et al.*⁵ when RA8 was added to platelet-rich plasma systems, we measured the clumping

Table 2. DURATION OF WHITE BODY FORMATION AT MAJOR INJURIES INFLECTED AT VARIOUS INTERVALS AFTER A SINGLE INTRAVENOUS INJECTION OF RA8

vity of rabbit platelet-rich plasma before and at intervals after an injection of *RA8*. Two samples of arterial blood were obtained, and *RA8*, 10 mg, was then given intravenously. Further arterial blood samples were obtained 2, 10–19, 20–40 and 60–90 min after the injection. Platelet-rich citrated plasma was prepared, and clumping response to ADP 1.5 µg/ml. was measured. For each sample the maximum fall in optical density observed after the addition of ADP was expressed as a percentage of the fall in optical density produced by high-speed centrifugation. The mean percentage fall in optical density for the two control samples was then taken as unity, and the clumping activity at the various times after *RA8* was expressed as a ratio of this control level. The *RA8* content of platelet-poor plasma was measured spectrofluorimetrically as described by Beisenherz *et al.*¹⁰. The results are shown in Table 5. There was a marked reduction in ADP-induced clumping 2 min after the injection of *RA8*; in the next sampling period this inhibition was less marked, and thereafter platelet-clumping activity had returned to its control-level.

Table 5. MEAN CLUMPING ACTIVITY WITH ADP 1.5 µg/ML. EXPRESSED AS A RATIO OF CLUMPING ACTIVITY IN CONTROL PERIOD, AND MEAN PLASMA *RA8* LEVELS, IN 6 RABBITS GIVEN 10 MG *RA8* INTRAVENOUSLY

Our results show that *RA8* profoundly modifies thrombus formation in injured arteries. The efficacy of topical applications, and our inability to demonstrate anything more than a transient change in the clumping activity of the circulating platelets, suggest that the agent is acting at the site of injury rather than on the circulating blood. Honour and Mitchell⁹ showed that thrombus formation in damaged vessels is brought about by compounds similar in properties to ADP and ATP. These are formed in the injured tissues, and are released into the lumen. *RA8* must interfere with this mechanism, either by cutting off the supply of thrombus-producing material or by producing an inhibitory substance.

RA8 has been shown to possess many interesting properties; it has marked vasodilator activity, produces some reduction in blood pressure, increases the rate and depth of respiration and produces bronchodilatation¹¹. The sites remain responsive to infused catecholamines, so simple sympathetic blockage cannot account for these changes, and Ungvárny *et al.*¹² have produced an alternative mechanism by showing that the agent produces a reduction in circulating catecholamines. *RA8* has other more fundamental actions, for it increases glucose consumption and reduces lactic acid formation in the hypoxic heart¹³. This finding may relate to the work of Frimmer *et al.*¹⁴, who showed that *RA8* was fixed by mitochondria and that it reduced the critical oxygen pressure in tissue culture studies. In ischaemic heart muscle, *RA8* increases the adenosine content; this increase results from decreased adenosine breakdown, rather than increased formation¹⁵. *RA8* might therefore interfere with white body formation in our injured arteries by allowing adenosine to accumulate at the injury site. However, topical and systemic *RA8* produce immediate inhibition, whereas there is a lag of some 30 min after systemic adenosine administration before an inhibitory effect is seen, while topical adenosine is inactive. It therefore seems probable that *RA8* interferes directly with the formation by the injury site of the white-body producing substance. Alternatively, it may affect the way in which the thrombus-forming message is propagated through the growing platelet mass. After injury, the first layer of platelets to adhere to the injury site must be capable of transmitting information to oncoming cells, and this process continues until the mass completely blocks the lumen. *RA8* might be acting on the circulating cells, and rendering them incapable of

propagating the injury message. The methods of studying platelets described here may not be capable of detecting this change. It would be of interest to know whether a major injury site rendered inactive with *RA8* is free from platelets, because the site is no longer producing the injury substance, or whether it is covered with a thin layer of platelets which are not propagating the injury message. We hope that electron micrograph investigation will help to resolve this question.

As *RA8* exerts such a powerful anti-thrombotic effect in injured arteries, could it be of value in the management of human vascular thrombotic disease? Mitchell¹⁶ has suggested that there are two alternative models of thrombus formation. In the first, hitherto normal circulating cells encounter an abnormal arterial segment. This is the situation in the injured rabbit cortical arteries which we have used to investigate *RA8*. In the second system, the circulating cells are already abnormal and are ready to adhere together; the location of the thrombus is determined, not by a message from an abnormal vessel wall, but by critical flow situations which permit cell collision and adhesion. We do not know which of these model situations is relevant to human disease, but would point out that our studies on the efficacy of *RA8* only pertain to thrombus formation in injured vessels, and we need further information on the action of *RA8* in man.

We have examined the effect of intravenous and oral *RA8* on the behaviour of human blood platelets⁵, and have shown that spontaneous platelet aggregation is reduced. Further examination of the clinical effects of *RA8* in thrombotic disease is clearly called for; unlike adenosine and 2-chloroadenosine, which would need detailed toxicity investigations before they could be used therapeutically, there is already a substantial corpus of information available about *RA8*. It appears to be remarkably non-toxic for a drug with such varied and powerful actions. Kadatz¹¹ showed that in mice the acute *LD*₅₀ for intravenous *RA8* was 150 mg/kg, while for oral administration it was 2,150 mg/kg. In long-term investigations, dogs were given 20 mg/kg/day, and rats received 100 mg/kg/day, without ill effect. We have used 600 mg/day by mouth in man⁵ obtaining plasma *RA8*-levels of up to 5 µg/ml. (10⁻⁵ M) without ill effect. One undesirable property of *RA8* might be its hypotensive effect; but in our anaesthetized rabbits we did not observe a reduction in pressure of more than 30 mm mercury. This is in accordance with the experience of Kadatz and Beisenherz¹⁷, who found a similar fall in blood pressure in dogs given 1.0 mg/kg (18.5 mm pressure reduction) to those given 4.0 mg/kg (23.8 mm pressure fall). We would therefore suggest that, in addition to the contribution made by *RA8* to the investigation of experimental thrombus formation, its lack of toxicity makes it a suitable material for clinical investigations in man.

A SEARCH FOR MUTATION IN CHEMICAL SYSTEMS AT STEADY STATE

By DR. GORDON ALLEN

National Institute of Mental Health, National Institutes of Health, Bethesda, Maryland

IN a steady state, a transient condition is maintained by continuous repetition. A complex system (for example, an organism) may be essentially in a steady state with respect to all major components, while minor components continue to change. A chemical mixture containing active reagents and continually replaced at a slow rate with freshly mixed solution approaches a steady state gradually. In such an 'open' system, systematic changes will presumably become smaller and smaller until they reach the level of random molecular events. A late, small systematic change and even a single molecular event might be detectable if amplified in some way.

Catalysis and especially autocatalysis seem to offer promise as amplifiers. In an open chemical system, a late-appearing minor product which inhibited or catalysed some early and major reaction might alter the number or proportions of the recognized components. Such a catalyst, interesting in itself, could be inferred from its effects on the system even if it was below the minimum concentration for direct assay. Thus, if one cannot deliberately use catalysis to detect late changes in an open system, one may investigate late changes in the hope of detecting interesting examples of catalysis.

With respect to molecular species having individually small probabilities of occurrence, the mixture would continue to change indefinitely. The more probable molecules would appear early and frequently; the least probable molecules, only singly and at long intervals. One of these rare molecules, even if it were a powerful catalyst, could not exert enough effect on other reactions to be detected during its lifetime. However, such a molecule might catalyse the formation of one of its own precursors. If in its lifetime the first molecule of catalyst increased the amount of precursor enough to make probable the formerly improbable synthesis of catalyst molecules, an autocatalytic system would result. The precursor and all derivatives including the catalyst would tend to increase until side reactions or the reverse of the catalysed reaction imposed a new steady state. If the reactants in the catalysed step were sufficiently abundant, one or more of the derivatives could reach detectable levels so that the new mixture would be recognizably different from the original.

This phenomenon, a late change due to the origin of a self-catalysing system, will be referred to as mutation in the common non-technical sense of the word and also in analogy with genetic mutations in organisms. Such a mutation can be defined operationally as a permanent change of composition in an established steady state such that the new composition can be induced in another similar mixture by a small inoculum from the original. It is not important whether the catalyst was present at very low concentration in the first steady state, or whether it appeared after an interval as a single, improbable molecule; these conditions are interchangeable with changes in volume and molar content of the system.

The general interest attached to homogeneous catalysis by organic molecules and particularly to simple self-reproducing systems¹⁻³ prompted the search described here. Despite negative results, it is reported as an investigation of evolution in a chemical system⁴, distinct from the already frequent and successful investigations of processes which could initiate chemical evolution⁵. Since there would be little reason for others to repeat the negative experiments, the findings and methods will not be described in complete detail. It is appropriate, how-

ever, to report the number and diversity of experiments and the analytical effort which will have to be improved if the demonstration of mutations in chemical systems is to succeed.

To maximize the number and rate of reactions and the likelihood of catalytic effects, it seems appropriate to use highly reactive compounds at moderately elevated temperatures and in maximal concentration consistent with a homogeneous solution. An approximate steady state can be maintained by periodic renewal of part of the mixture. Recognition of late changes which yielded new products would require only standardized analysis for detection, not identification of components. One more new spot appearing during chromatography after a solution had apparently stabilized, or a sharp change in relative intensity of certain spots, would direct attention to possible catalysis by a late product. A mutation would then be indicated if the old and new chromatographic results could be produced side-by-side in simultaneous analyses of two freshly-started solutions, one of which had been 'seeded' with the old solution. Even if no change had been detected in the original steady state, a reproducible difference between seeded and unseeded solutions would demonstrate an effect of inoculation that might represent catalysis.

The experiments were conducted in 100-ml. samples in side-arm flasks half immersed in oil at 90° C. The flasks were connected through reflux condensers to a slow-flowing stream of nitrogen under slight positive pressure. Most of the seeding tests were conducted in smaller samples in side-arm test-tubes with cold-finger condensers. The basic reagents, formaldehyde and cyanide, were selected as the most reactive one-carbon compound readily obtainable in a high state of purity. Ammoniacal allyl alcohol, diacetyl and pyruvic acid were added singly or in combination to some solutions, and in two solutions cyanide was omitted. Each of nine combinations was replicated in solutions buffered at pH 7 and pH 9 with sodium, chloride and phosphate ions. Table 1 shows the main reagents in the eighteen experiments.

Experiments 17 and 18 were initiated just two months before the end of the project, but the other experiments ran for between 14 and 20 months. The initial renewal schedule was 10 per cent daily, and after 2-4 months the interval was lengthened to 20 per cent semi-weekly or 10 per cent weekly in different experiments. A number of the solutions were eventually modified by addition of minerals in catalytic quantities: MgSO₄, CaCl₂, CuSO₄, FeSO₄, MnCl₂, ZnCl₂, KI, I₂, and reduced sulphur as cysteine. Continuous ultra-violet radiation⁶ was supplied in experiments 17 and 18 and in the last four months of experiments 13-16 by means of pencil-shaped mercury vapour lamps mounted in the side-arm stoppers and dipping under the surface of the solutions.

Samples were analysed by evaporation to dryness under nitrogen at 40° C, and the initial distillate was collected

or gas chromatographic analysis. The residue after distillation was extracted in turn with methyl acetate and ethanol and was finally re-dissolved in water. The three resulting extracts were chromatographed in two dimensions on thin layers of silica gel. Three pairs of solvent mixtures were devised to give good separations of each extract in the early experiments (Fig. 1), but for the more complicated solutions these systems were supplemented with one-dimensional chromatography in other solvents (Fig. 2). The dry chromatograms were in most cases sprayed with alkaline KMnO_4 , yellow spots on the pink background were marked to indicate their order of appearance, and the results were recorded as negative photographic prints before they began to fade. In most of the seeding tests, carbon-14-labelled formaldehyde and/or cyanide were used and autoradiograms were made⁶. Some chromatograms, particularly in the seeding tests, were examined by means of more sensitive or more specific location reagents or were viewed under ultra-violet light.

Fig. 1. Typical thin-layer chromatograms of solution 3 in the steady state. A, Methyl acetate extract; B, methanol extract; C, extracted residue. Each fraction was chromatographed with a different, appropriate pair of solvents, but there is some duplication of separated compounds in successive chromatograms

Fig. 2. Methyl acetate extracts chromatographed in a water-free system to separate compounds that coalesced near the front in the usual two-dimensional analysis (compare with Fig. 1 A). Extracts of four pairs of solutions obtained in seeding tests of experiments 15, 16, 17, 18; the left member of each pair had been seeded

Hydrogen cyanide in aqueous ammonia is known to produce a large variety of biologically interesting compounds spontaneously. Oro⁷ identified seven compounds including adenine. At least 75 ninhydrin-reacting compounds have been distinguished after hydrolysis of the products and at least fifty compounds absorb or fluoresce in ultra-violet light⁸. The reactions of alkaline cyanide with formaldehyde also proceed rapidly and yield a variety of compounds⁹. In the experiments recorded here, cyanide and formaldehyde yielded 27 reproducible spots on chromatograms of the entirely non-overlapping aqueous and methyl acetate extracts when permanganate was the location reagent. Autoradiography revealed as many as 48, and many additional spots could be detected by fluorescence. Four strong spots were ninhydrin positive and many others revealed nitrogenous content by reacting with sodium hypochlorite or tertiary butyl hypochlorite. A few spots gave one or more positive tests for double bonds, phenols, esters and aldehydes. Gas-liquid chromatography of the formaldehyde-cyanide mixtures in a steady state revealed from three to five products; but the method would not have detected highly polar compounds.

Addition of other reagents resulted in more numerous products. Thus, gas chromatograms of solutions 15 through 18 all had at least 19 indicated peaks in addition to those obtained with the reagent blanks (Fig. 3). Solutions containing diacetyl acquired a surface film and a variable amount of brown turbidity or sediment. Changes in renewal schedule and addition of minerals had surprisingly little effect on most of the chromatograms. Ultra-violet light had little effect in the turbid solutions, but changed solutions 13 and 14 rather extensively. In addition to the regularly appearing spots, others occurred in only a few analyses or were poorly differentiated. Some which appeared late in the investigation could be attributed to improvements in technique or to changes in the experiments. While the less-reliable spots could not be taken as evidence of mutation in themselves, they could be examined to advantage in the seeding tests, in which seeded and control solutions were analysed simultaneously and compared in fine detail (Fig. 2).

The reactions proceeded rapidly in all solutions, yielding yellow or red-brown colour in the first hour and going on to nearly black in many of the mixtures. Nearly all spots which appear on chromatograms could be found at 24 h, and after four days there were only minor changes. In experiments 1-8, control solutions were maintained without renewal for several weeks; they yielded pro-

Fig. 3. Gas-liquid chromatogram of volatile fraction, solution 17. The two deflexions below the base-line correspond to increases in sensitivity by factors of 200 and 2, respectively. The second peak coincides with that of one reagent, allyl alcohol. Column used: 'Castorwax' on 'Chromosorb W' (HMDs) (Wilkens Instrument Co.), 2 meters

gressively simpler chromatograms, and alkaline solutions 1 and 5 lost colour.

No good evidence of mutation was found. A few differences between seeded and control solutions were observed, but these were either not reproducible or could be attributed to late reaction products in the seeding solutions, detectable at the effective dilution of about 1:20. The only observed late change in a stable mixture was seen in the physical characteristics of solution 1. After about five months this solution became relatively resistant to evaporation in the analytical procedure. This change did not coincide with any detectable change in the chromatograms; it was not perpetuated in seeding tests and disappeared from the flask within three weeks.

Failure to demonstrate mutations in these experiments does not, of course, prove that mutations cannot occur. The variety of reagents and conditions was limited and detection of products was not exhaustive even at concentrations of more than 10^{16} molecules in 100 ml. How-

ever, the total number of molecular species produced an given an opportunity to catalyse ongoing synthesis of their own precursors was probably many hundred. In addition, contamination by micro-organisms must have added innumerable compounds of known biological activity. The reaction conditions were intentionally inimical to reproduction by whole organisms and would have quickly degraded their enzymes, but some native compounds and many modified ones would have been stable. If any of these contaminating compounds could have been produced in one or more of the solutions, they had an opportunity to catalyse their own synthesis or that of their precursors.

It is possible that similar experiments with different reagents might yield detectable mutations; in that event the required catalysis may depend on rather specific reagents and conditions, and is not a frequent phenomenon at low levels of molecular complexity. It is also possible that some of the molecules occurring in these experiments did catalyse steps in their own synthesis, but that the inefficiency of the catalysis or slow intervening steps prevented detectable change. Several such mutations would have to accumulate and provide a more or less complete 'metabolic' system¹ before any catalysts could reach concentrations that would alter the major components. If such a low level of efficiency is characteristic, mutation can be detected only in more prolonged experiments, by more sensitive analytic techniques, or by the application of quantitative and statistical methods.

These experiments were initiated at the Geophysical Laboratory, Carnegie Institution of Washington, under the sponsorship of Dr. P. H. Abelson. I thank Dan F. Bradley of the National Institutes of Health, for his advice during a training period, and Frank Eisenberg, jun., Seymour L. Friess, Thomas C. Hoering, Patrick L. Parker and Hans Weil-Malherbe for further advice.

PLAQUE-FORMATION BY NON-IMMUNE AND X-IRRADIATED LYMPHOID CELLS ON MONOLAYERS OF MOUSE EMBRYO CELLS

By GÖRAN MÖLLER and ERNA MÖLLER

Department of Tumour Biology, Karolinska Institutet Medical School, Stockholm

THE demonstration that immune lymphoid cells are capable of killing histo-incompatible target cells *in vitro* has greatly facilitated the examination of the mechanism of cellular immunity in tissue transplantation^{1,2}. Various characteristics of the cytotoxic effect of humoral antibodies and sensitized cells on different targets appear to justify the conclusion that they act by different mechanisms. Thus, cytotoxicity caused by cellular immunity does not require the participation of complement in contrast to the action of humoral isoantibodies. Furthermore, target cell death was detected after 24–48 h, subsequent to treatment with immune lymphoid cells, whereas humoral antibodies killed within 1 h in the presence of complement³. As a matter of fact, an antagonistic relationship exists between cellular and humoral immunity in tissue culture and *in vivo* as well^{3,4}: pretreatment of neoplastic target cells with humoral isoantibodies inhibited the cytotoxic effect of immune

lymphoid cells partly or completely, presumably by competition for the same antigenic determinants.

A fundamental difference was revealed between cellular and humoral immunity by the finding that target cell death subsequent to treatment with immune lymphoid cells could be ascribed to close contact with the foreign histocompatibility antigens carried by the lymphoid cells². It could be shown that normal allogeneic lymphoid cells were as efficient in killing target tumour cells *in vitro* as immune cells, provided that they were aggregated to the targets by phytohaemagglutinin or heterologous antibodies; aggregation of isogenic lymphoid cells had no detectable effect. The cytotoxic action of non-immune lymphoid cells was not caused by the induction of a primary immune response *in vitro* since semi-isogenic F_1 hybrid lymphoid cells killed the parental target cells efficiently, although they were genetically incompetent to respond immunologically². The

results suggested that immune lymphoid cells were equipped with a specific receptor making them capable of becoming attached to the target cells; target cell death was not due to an immunological reaction, however, but appeared to be related to a non-immunological recognition process of antigenic and/or structural incompatibility, leading to cell death by so far unknown reactions. This phenomenon has been termed *antigenic recognition*.

In the work recorded here a plaque-technique was used to evaluate the effect of normal lymphoid cells aggregated to monolayers of embryonic target cells. Particular interest has been focused on the importance of genetic disparity between the non-immune lymphoid cells and the embryonic targets.

Monolayers of mouse embryo cells were prepared by treating fragments of embryos (14–19 days old) with 0.25 per cent trypsin for 1 h at room temperature. The cells were washed and suspended in lactalbumin in Earle's solution supplemented with 10 per cent foetal calf serum. 10^7 Trypan blue unstained cells were added to each 10 cm diameter Petri dish and 3×10^6 cells to each dish with 5 cm diameter. After 24–48 h inoculation the medium was replaced with Parker's Medium 199 supplemented with 10 per cent calf serum and containing phytohaemagglutinin diluted 1/50–1/100. One hour later 0.1 ml. of a lymphoid cell suspension containing $5-10 \times 10^6$ cells was carefully dropped on to a limited area of the monolayer culture. The lymphoid cells usually occupied an area with a diameter of 1–2 cm, but did not spread further and became firmly fixed to the monolayer culture due to the presence of phytohaemagglutinin. Each Petri dish received lymphoid cells at 3–4 different spots, one suspension always containing isogenic cells.

In some experiments the lymphoid cells were irradiated with 1,500 r. 1–2 h prior to the addition on to the monolayers. Irradiation was carried out with cell suspensions in Petri dishes. The dose of irradiation was sufficient to prevent the division of the lymphoid cells completely as shown by their failure to incorporate thymidine labelled with carbon-14 subsequent to stimulation with phytohaemagglutinin. In contrast a marked stimulation of isotope incorporation was observed with non-irradiated cells after 24 h.

The effect of aggregation of non-immune lymphoid cells on embryonic target cells was evaluated by the appearance of plaques in the monolayer culture at the site of lymphoid cell introduction (Fig. 1). An analogous technique has been described by Granger and Weiser⁵ for the detection of cytotoxic effects mediated by immune macrophages on monolayer cultures of neoplastic cells. In our system the plaques were seen macroscopically as a clear circular area in the monolayer (Fig. 1). Microscopically the plaques were found to contain a few scattered embryo cells, usually surrounded by aggregated lymphoid cells (Fig. 2). In cases where no plaques developed the monolayer cells were intact and surrounded by dense aggregates of lymphoid cells.

The addition of allogenic or semi-isologous F_1 hybrid spleen or lymph node cells on to monolayers of parental embryo cells in several different strain combinations led to the appearance of plaques, whereas isogenic lymphoid cells had no detectable effect (Table 1, Exps. 1–7). The plaques appeared at the same time in each experiment, but the time needed for detectable plaque formation varied between 1 and 6 days in different experiments. In the majority of the experiments the cultures were observed for 4–7 days after the first appearance of the plaques, but no further plaques were found to appear. It cannot be stated with certainty that plaque formation was caused by target cell death, but the results are in agreement with the earlier findings, demonstrating that both F_1 and allogenic cells were capable of killing parental neoplastic target cells *in vitro*. The previous investigations led to the conclusion that close contact with foreign histocompatibility antigens resulted in the target cell

death. It was of considerable interest, therefore, to study the effect of parental lymphoid cells on F_1 hybrid targets, since the parental lymphoid cells are not expected to contain any antigens foreign to the target cells.

Non-immune parental lymph node or spleen cells were found to be fully competent to induce the appearance of plaques in the majority of cases studied (Table 1, Exps. 8–13). Thus, parental lymphoid cells behaved as allogenic cells in this respect. However, exceptional results were obtained with some parental lymphoid cells. Thus, CBA, C3H and DBA/2 cells failed to induce plaques on hybrids with strain A as the other partner, although both non-immune A parental lymphoid cells and allogenic cells were efficient. It is not possible by the technique to differentiate between a complete non-reactivity and a decreased efficiency of the lymphoid cells. However, recent findings⁵ obtained with a quantitative test system described previously^{2,3} showed that non-immune parental lymphoid cells of the genotypes mentioned killed efficiently semi-isogenic F_1 hybrid targets. It seems possible, therefore, that the present results are due to quantitative factors. The failure of CBA, C3H and DBA cells to affect the hybrid targets was not limited to hybrids with strain A as the other partner, but was also with (A.SW \times CBA) F_1 hybrids and with allogenic (5M) target cells. A discrepancy between the effect of two parental cells on hybrid targets was also noticed in one experiment with A and C57BL

Fig. 1. Macroscopic appearance of plaques on (A \times C57BL) F_1 mouse embryo cells. At the indicated sites were added (A \times C57BL) F_1 (1), A (2) and A.CA (3) X-irradiated (1,500 r.) lymphoid cells.

Fig. 2. Microscopic appearance of plaques on (A \times C57BL) F_1 mouse embryo cells subsequent to addition of irradiated A lymphoid cells. The destroyed monolayer is seen in the upper part of the figure, whereas the uninterrupted monolayer is seen in the lower part.

cells on F_1 embryo cells: only the A lymphoid cells induced plaques. However, in another experiment the $C57BL$ cells were efficient, again emphasizing the importance of quantitative factors in the formation of plaques.

The findings that parental lymphoid cells are capable of killing hybrid targets as a rule require a modification of the concept that *in vitro* cytotoxicity is caused by target cell contact with foreign histocompatibility antigens, since the parental lymphoid cells do not contain any foreign isoantigens. The experimental findings might be explained by two alternative possibilities: (1) Target cell death is the consequence of close contact with a structurally different but antigenetically not necessarily incompatible cell surface. Although the parental lymphoid cells do not contain isoantigens foreign to the hybrid targets, the cell surface structures are necessarily different. (2) The lymphoid cells are killed primarily by the contact with the foreign antigens on the target cells and their death affects the viability of the target cells secondarily. The correct alternative is not yet known.

Since F_1 lymphoid cells are efficient against parental embryonic target cells the possibility that plaque-formation can be ascribed to a primary immune response is unlikely. However, in the experiment with allogenic and parental lymphoid cells the necessary requirements for an immune response are present. Although the tissue culture conditions and the speed of the reaction make

this possibility less likely, experiments were performed to examine the effect of heavily irradiated lymphoid cells on the monolayer cultures. The cells were given 1,500 r, which completely inhibited the phytohaem agglutinin-induced stimulation of DNA synthesis. It was found that X-irradiation did not detectably inhibit the ability of hybrid lymphoid cells to cause plaques on parental embryo cells (Table 1, Exps. 5 and 7). Neither did X-irradiation affect the plaque-forming efficiency of allogenic and parental lymphoid cells (Table 1, Exps. 5, 7, 10). Thus, lymphoid cell division is not a necessary prerequisite for the effect.

A few experiments were performed to study the ability of erythrocytes to induce plaques on monolayer cultures. Addition of allogenic or parental erythrocytes on to embryonic targets did not result in plaques, whereas the same number of lymphoid cells were efficient in the same Petri dishes (Table 1, Exps. 1 and 4). Since red cells are known to contain considerably fewer $H-2$ isoantigenic determinants than lymphoid cells⁶ it cannot be excluded that quantitative factors regarding antigenicity were responsible for the discrepancy.

The results reported substantiate the earlier conclusion that a non-immunological recognition process is initiated by the close contact between antigenically and/or structurally incompatible lymphoid cells and target neoplastic and embryonic cells, which results in damage or death

lgl = lymph node cells.

the target cells. Lymphoid cell division is not involved in the process. It appears likely that the target cells are led as a consequence of contact with incompatible tigens or surface structures carried by the normal lymphoid cells and not by immunological reactions of conventional types. According to this concept cellular immunity might be the expression of a more general biological phenomenon, which may function as a cell-to-cell homeostatic mechanism tending to eliminate cells with altered cell surface structures and which may be, therefore, important as a control mechanism against neoplasia and other aberrations of cell differentiation.

MEASUREMENT OF UNSTEADY STATE GROWTH RATES OF MICRO-ORGANISMS

By PROF. R. I. MATELES, D. Y. RYU and T. YASUDA

Department of Nutrition and Food Science, Massachusetts Institute of Technology

THE measurement of growth rates of micro-organisms by determining the rate of change of the concentration of a cellular component such as protein, DNA, or RNA is well established¹, as is the use of dry weight or optical density measurements on the growing culture to approximate the dry weight². Most frequently these techniques are applied during the phase of growth known as 'log phase', and the growth rate is determined simply by plotting the logarithm of the optical density (or dry weight, protein concentration, etc.) versus time. Because the growth rate remains constant for at least several generations under most conditions of culture, the accuracy of the estimation is increased by plotting a number of points and determining the best straight line, the slope of which is used to calculate the growth rate.

For studies of growth rates under conditions where the growth rate is changing with time, these techniques are unsatisfactory because a 'best straight line' does not exist, and estimation of the slope of a curved line is not reliable. We have found that a technique combining continuous culture with continuous indirect measurement of the cell mass concentration permits accurate estimation of unsteady-state growth rates.

The method is based on the principle of measuring continuously the concentration of a single nitrogen source in the medium on which a micro-organism is grown in continuous culture. Typically, the nitrogen source is an ammonium salt, although the use of an amino-acid or other nitrogen source would be equally satisfactory, provided that an assay exists suitable for use with a continuous analyser such as the Technicon 'AutoAnalyzer'.

By writing material balances on the growth vessel, the following equations are obtained³:

$$\frac{dN_c}{dt} = \mu N_c - DN_c \quad (1)$$

and:

$$\frac{dN}{dt} = DN_0 - DN - \mu N_c \quad (2)$$

where N represents the concentration of source nitrogen in the growth vessel, N_c represents the concentration of cellular nitrogen in the growth vessel, N_0 represents the concentration of source nitrogen in the incoming medium, μ represents the specific growth or nitrogen assimilation rate, D represents the dilution rate or the ratio of medium flow rate to medium volume contained in the growth vessel, and t represents time. In the absence of excretion of nitrogen compounds and significant changes in intracellular amino-acid pools, the nitrogen assimilation rate will correspond to the growth rate⁴.

The growth rate determined in this manner would correspond to a growth rate measured by following the increase in Kjeldahl nitrogen incorporated by the cells. For the case in which the nitrogen source is made the growth-rate-limiting nutrient, the following equation⁵ also applies.

$$\mu = \frac{\mu_{\max} N}{K_s + N} \quad (3)$$

in which μ_{\max} represents the maximum growth rate of the cells in the presence of an excess of limiting nutrient, and K_s is a constant. For nutrient-limited conditions in a continuous culture, the concentration of limiting nutrient in the culture vessel at steady-state is independent of its concentration in the incoming medium.

When N_0 is held constant, equation (2) can be rearranged to yield the growth rate in terms of the other variables:

$$\mu = D - \frac{dN}{dt} / (N_0 - N) \quad (4)$$

Thus, in order to calculate the instantaneous growth rate, one need only determine from the recorder-chart the value of N at some time t , estimate the value of dN/dt by numerical methods, and knowing D and N_0 , calculate the growth rate, μ .

The sensitivity of this technique resides in the fact that changes in N are easier to observe and measure accurately than changes in N_c , as may be seen from Table 1.

As Table 1 shows, during the first minute after the change in growth rate, the concentration of ammonium nitrogen in the medium more than doubles while the cell nitrogen concentration falls by less than 2 per cent. The change in ammonia concentration is readily measurable with a Technicon 'AutoAnalyzer', while it would require unusually precise measurements to detect a difference in cell dry weight or optical density of 2 per cent.

We have applied this method to the problem of determining the behaviour of a microbial culture during a 'shift up'¹. In this case the shift up was obtained by increasing the dilution rate of the culture, rather than by shifting to a richer medium capable of supporting faster growth. The organism used was *Escherichia coli* B, growing at 37° C in a well-stirred growth vessel holding 200 ml. of *M*-63 medium⁶ containing glycerol as a carbon source and ammonium sulphate (63 mg of ammonium nitrogen/l.) as a nitrogen source. The medium was fed from a reservoir by a 'Sigmamotor' pump. A sample of broth and cells from the growth vessel was taken continuously by a Technicon 'AutoAnalyzer', and the concentration of dissolved ammonia was determined using an alkaline phenol-hypochlorite technique⁷. Glucose in the medium interfered with this assay and therefore glycerol was used as carbon source.

Table 1. CHANGES IN THE CONCENTRATION OF CELLULAR NITROGEN (N_c) AND MEDIUM NITROGEN (N) IN A CONTINUOUS CULTURE AFTER THE MICRO-ORGANISM'S GROWTH RATE SUDDENLY FALLS TO ZERO

Time (min)	N (mg/l.)	N_c (mg/l.)
0	1	99
1	2.6	97.4
2	4.2	95.8
3	5.8	94.2

Calculations made for a continuous culture with, $D = 1.0 \text{ h}^{-1}$; $N_0 = 100 \text{ mg/l.}$

Fig. 1. Results of an unsteady-state experiment in which ammonium nitrogen was the limiting nutrient

Fig. 2. Evidence that the jump in growth rate (see Fig. 1) is not an artefact. N_1 represents the steady-state concentration of ammonium nitrogen in the growth vessel prior to the increase in dilution rate

Prior to the unsteady-state growth rate measurements, a steady state was maintained for at least 15 h. Then an increase in dilution rate was made, the concentration of ammonium nitrogen determined as a function of time after the step change in dilution rate, and the instantaneous growth rate calculated from data obtained from the plot of N versus time. The calculations were carried out on an IBM 7094 digital computer because they involved the manipulation of considerable data.

The results of a typical run are shown in Fig. 1, for which $D_1 = 0.41 \text{ h}^{-1}$ and $D_2 = 0.83 \text{ h}^{-1}$. It appears that the growth rate rose about 0.2 h^{-1} immediately after the dilution rate change and then slowly rose further, overshooting a new steady-state growth rate, and then settling back into a steady state. That the instantaneous rise is real, and not an artefact introduced through numerical differentiation, is shown in Fig. 2, in which $\ln(N_0 - N_1)/(N_0 - N)$ versus time is plotted. The slope of the curve is equal to $D - \mu$ (ref. 8). The solid line indicates the results that would be obtained if the growth rate remained at the value it had prior to the dilution rate change. Since the actual line is not tangent to the solid line, it indicates that a real increase in growth rate occurred at the time of the dilution rate increase, and since the line has a constant slope for about 15 min, that the growth rate stayed constant at 0.63 h^{-1} for about 15 min before increasing further over the course of the next few hours.

Table 2 shows the results of a series of experiments made at a number of dilution rates and dilution rate changes. For small dilution rate changes, the perturbation in ammonium nitrogen concentration was absent or small, indicating that the growth rate accommodated the dilution rate change, whereas when the dilution rate change increased, the ability of the cells to increase their growth rate was not sufficient and a large perturbation in ammonium nitrogen was observed.

In order to determine whether Monod's equation (equation (3)) could be used to represent unsteady-state growth rates, equations (1), (2) and (3) were solved by numerical method using the digital computer. Regardless of the magnitudes of the constants μ_{max} and K_s or the parameters N_0 and D , the transient growth rate calculated on the assumption that Monod's equation is applicable always lacks a maximum and is a smooth transition between the two steady states⁹. Clearly the experimental curve (Fig. 2) departs significantly from Monod's model. Thus, during transient operation of a continuous culture Monod's equation may not be used to relate growth rates and concentrations of limiting nutrient.

In contrast to the results of Kjeldgaard, Maaløe and Schaechter¹, we have found that the cell can increase its rate of protein synthesis immediately after a shift up, and that this small increase is then followed by a prolonged gradual increase. The discrepancy between the present findings and the earlier ones may be ascribed to the relative insensitivity of the direct measurement of the growth rate by following changes in optical density, or protein concentration as practised by the earlier workers.

The possibility that the immediate increase in the nitrogen assimilation rate, here interpreted as the growth

Fig. 3. Incorporation of uracil- ^{14}C and l-leucine- ^3H by *E. coli* B before and after change in dilution rate. The medium contained 10 mg of l-leucine and 10 mg of uracil per litre in addition to the ingredients contained in M-63 medium used in the previous experiment. Ten μC of l-leucine- ^3H and 10 μC of uracil- ^{14}C were added to the culture 9.1 min prior to the change in dilution rate. At the time indicated by the arrow, the dilution rate was increased from 0.45 h^{-1} to 1.16 h^{-1} . Samples were taken approximately at 1-min intervals, added to an equal volume of ice-cold 5 per cent TCA, and at the conclusion of the experiment filtered through a Millipore filter, washed, and counted by a liquid scintillation counter. The counts were corrected for dilution of the radioactive tracer in the culture vessels by incoming medium containing only unlabelled l-leucine and uracil, and for the cell concentration

ate, represented a preferential increase in the rate of RNA synthesis alone rather than an increase in the rate of both protein and RNA synthesis can be excluded on the basis of the experimental results depicted in Fig. 3. The results clearly indicate that at the time of the change in dilution rate, the rate of incorporation of both L-leucine- ^3H and uracil- ^{14}C increased sharply, implying that the rates of protein and RNA synthesis increased.

The results recorded here further indicate that protein and RNA biosynthetic activities in the cell are not at the maximum levels of their capacities under the given conditions, since the rate of nitrogen assimilation is increased immediately when the feed rate of limiting nutrient is increased.

In the experiments described here, it was found that all the nitrogen in the medium could be accounted for as free ammonium nitrogen; the cells did not excrete any intermediary products of nitrogen metabolism. This might not always be true, particularly under conditions in which the carbon source is the limiting nutrient, and it would be desirable to make certain that the nitrogen in the medium is all in the form which is being assayed. This can be done by collecting on ice a portion of effluent, centrifuging to remove cells, and comparing the ammonium nitrogen analysis of the cell-free medium with a total nitrogen analysis.

These results clearly indicate that, contrary to the views of Herbert¹⁰, a significant lag in adjustment of growth rate to dilution rate does exist, and that this lag must be taken into account in experimenting with single or multi-stage continuous culture systems. For example, determining the apparent maximum growth rate (μ_{max}) from the slope of a plot of $\ln x$ versus t may underestimate the true μ_{max} .

It should be noted that it is not necessary for the nitrogen source to be the limiting nutrient in order to use this technique for studying unsteady-state growth rates. All that is required is for the concentration of the nitrogen

source in the growth vessel to be low relative to its concentration in the reservoir. This could be accomplished, for example, by having the carbon source as limiting nutrient and using a concentration of nitrogen source in the medium sufficient to leave five or ten parts per million unused under steady-state condition. For most cases, this concentration will be in excess, that is, the growth rate of the organism will not be affected by small changes in the concentration of nitrogen source. Using this technique it would be possible to study the effects on growth rates of concentrations of inhibitory substances too low to study by standard techniques, because they would not stop growth entirely but only reduce the growth rate slightly for short periods of time.

The calculations were performed on an IBM 7094 digital computer at the Computation Center of this Institute.

PROTONATION EQUILIBRIA AND ALKALINE HYDROLYSIS OF GLYCINE ETHYL ESTER

By DR. MARGARET ROBSON*

Department of Chemistry (University of St. Andrews), Queen's College, Dundee

IN the past decade, interest has developed in the interaction of metal ions with biologically important compounds, for example, amino-acid esters and peptides. The complexing tendencies of such molecules, the stabilities and reactivities of the resulting complexes have been investigated¹⁻³, but very little systematic work has been carried out. The following account describes preliminary work towards such an investigation.

The proton ionization equilibria of glycine ethyl ester and glycine, and the alkaline hydrolysis of the ester, have been examined prior to a detailed analysis of the metal ion complexing and catalysis.

The ionization constants were measured at $25^\circ \pm 0.05^\circ \text{C}$ and $0^\circ \pm 0.05^\circ \text{C}$; and at three differing ionic strengths in the case of the ester. Values for the pK_a of glycine⁴ have been reported and temperature coefficient data⁵ are available. The glycine work was therefore carried out mainly as a check on the accuracy of the ester measurements. pH titrations were carried out using a Radiometer pH-stat titrator, coupled with a Radiometer pH scale expander. Alkali was added from an all-glass micrometer syringe. The pH assembly was operated manually. Where necessary, the ionic strength was brought to the required value by addition of potassium bromide solution. pK_{a1} at 25°C for glycine was estimated by decreasing the

pH of the initial solution to approximately 2.5 by addition of hydrochloric acid. pK_a values were calculated from selected points (on the average, sixteen points were chosen) along the titration curve using conventional methods⁶. An average of five titrations were performed for each ionic strength. pH values were converted to concentrations using the Davies equation⁷, and equilibrium constants thus calculated (Table 1) are concentration quotients. For the ester, drifting values, which were a result of hydrolysis, were obtained at high pH.

pK_a values independent of ionic strength are expected in the ionization of glycine ethyl ester ($\text{H}^+\text{E} \rightarrow \text{H}^+ + \text{E}$), and this is confirmed by the results. The scatter in values at 25°C is much higher than at 0°C . This is expected as a consequence of the increased rate of hydrolysis at 25°C . The average value at 25°C , 7.72, agrees well with 7.73 reported by Emerson and Kirk⁸, and with an estimated value of 7.76 (ref. 9) based on a ΔpK ($\text{NH}_3\text{CH}_2\text{COO}^-$

Table 1

Acid	Temp.	Ionic strength	pK_{a1}	pK_{a2}
Glycine ethyl ester hydrochloride	25°C	0.05	7.71 ± 0.01	—
		0.075	7.74 ± 0.01	—
		0.100	7.76 ± 0.02	—
		0.01	8.36 ± 0.00	—
		0.10	8.46 ± 0.01	—
Glycine	25°C	0.1	2.38 ± 0.02	9.61 ± 0.01
		0.1	—	10.30 ± 0.00
	0°C	0.1	—	—

* Now Dr. Margaret Robson Wright.

$\text{NH}_3\text{CH}_2\text{COOEt}$) of 2.02. It is also close to the value for the methyl ester, 7.68, found by Edsall¹⁰.

pK_a values strongly dependent on ionic strength are expected for the second ionization of glycine ($\text{H}^+\text{G} \rightleftharpoons \text{H}^+ + \text{G}^-$), and approximately independent of ionic strength for the first ionization ($\text{H}^+\text{G} \rightleftharpoons \text{H}^+ + \text{G} + \text{H}^+$). Thus for comparative purposes a thermodynamic pK_{a2} , 9.84₃, was calculated from the second ionization using the equation:

$$\log K_{T,D} = \log K_c - \frac{2Az^2\sqrt{I}}{1 + \sqrt{I}} + 0.2z^2I$$

This value compares favourably with that of 9.78₀ (ref. 5), as does the value reported here, 2.33₈, with that listed⁵, 2.35₀, for the first ionization.

Table 2 lists ΔG° , ΔH° , ΔS° and $T\Delta S^\circ$ values for the ionizations, assuming ΔH° independent of T from 0° C to 25° C, along with analogous values calculated from Edsall's¹⁰ data on glycine methyl ester over the smaller temperature range (20°–30° C), and from tabulated data⁵ for the second ionization of glycine.

Differences in pK_a for the processes

are predominantly due to a difference in ΔS° for the ionization process. Qualitatively a process, electrically neutral species \rightarrow 2 ions, would be expected to have a more negative ΔS° than the process ion \rightarrow ion. This is, in fact, observed, while no great difference in ΔH° is found. Values of ΔS° for the ionization of carboxylic acids¹¹ (for example, -22 cal mole⁻¹ deg.⁻¹ for acetic acid) are considerably more negative than that for the second ionization of glycine. The low value of $|\Delta S|$ for glycine seems related to the existence of the dipolar zwitterion. Comparable ΔS° values to that of the ester are found in monobasic amine acids¹¹.

The alkaline hydrolysis of glycine ethyl ester has been investigated at an ionic strength of 0.1, and at 25° C and 0° C over a wide pH range. The kinetics were followed by a pH-stat device which enables the pH to remain constant by automatic and recorded addition of alkali. The accuracy of the results is limited by the accuracy with which the machine can maintain a constant pH. The following equilibria and reactions are involved:

It follows that the total alkali uptake, assuming the reaction to go to completion, is given by the expression:

$$V_\infty = [\text{ester}]_{\text{initially}} \left\{ 1 + \frac{1}{1 + \frac{K_1}{[\text{H}^+]}} - \frac{1}{1 + \frac{K_2}{[\text{H}^+]}} \right\}$$

All pseudo first-order rate plots were calculated on this basis. At high pH, where the runs were taken to completion, good agreement with the observed V_∞ was obtained. Second-order rate constants were estimated from the pseudo first-order rate constants by division by

0° C	$k^* = 230$	$k = 8.5$
25° C	$k^* = 1,130$	$k = 35.6$
	$E_A^* = 10.6$	$E_A = 9.4$
	$A^* = 7.4 \times 10^{10}$	$A = 3 \times 10^9$
	$\Delta S^\circ_{298} = -12$	$\Delta S^\circ_{298} = -23$

Rate constant in units: 1 mole⁻¹ min⁻¹.
Activation energy in units: kcal mole⁻¹.
Entropy of activation: cal mole⁻¹ °K⁻¹.

the hydroxide ion concentration calculated from the pH of the run (or average pH if drifting with time occurred, and the Davies equation⁷). Second-order rate constants were found to vary with hydrogen ion concentration. The pH range extended from 9.6 to 11.7. Fig. 1 gives the results for some 50 runs at 25° C.

There is a large scatter of points, about the line drawn, but a 'deviations plot' shows the scatter to be random, in marked contrast to the situation where no variation with concentration is assumed.

If the kinetics follow the scheme outlined previously and corrections have been made for the protonation equilibria involved:

$$k_{\text{obs}} a = k^*[\text{H}^+\text{E}] + k[\text{E}]$$

where a represents the initial total ester concentration (that is, $[\text{H}^+\text{E}]_0 + [\text{E}]_0$). If, to a first approximation, $[\text{E}] = a$, then:

$$k_{\text{obs}} = k + \frac{(k^* - k)[\text{H}^+]}{K_1}$$

A higher approximation would give:

$$k_{\text{obs}} = k + (k^* - k) \frac{[\text{H}^+]}{K_1} \left\{ 1 - \frac{[\text{H}^+]}{K_1} \right\}$$

Such a correction is well within the experimental errors and, therefore, pointless.

Thus an observed rate constant varying with $[\text{H}^+]$ should be found, and a plot of $k_{\text{obs}} V [\text{H}^+]$ should give k as intercept, and k^* calculable from the gradient. Table 3 summarizes the data for experiments at 25° C and for a few experiments at 0° C. Provisional estimates of E_A , A , ΔS° are given.

The Bjerrum¹² type equation representing the effects of electrostatic interactions between a charged substituent and the reaction site in the transition state is:

$$\frac{k^*}{k} = \exp \left(\frac{-z_1 z_2 e^2}{DkTR} \right) \quad (5)$$

where k^* and k are the rate constants for reactions involving the charged molecule and uncharged molecule, respectively, $z_1 e$ is the charge on the initial molecule, and $z_2 e$ is the charge developed at the reaction site. R is the distance between the charges.

Thus:

$$E^* - E = \frac{Ne^2 z_1 z_2}{DR} \left[1 + \frac{T}{D} \frac{dD}{dT} \right] \quad (6)$$

where E^* and E are the activation energies for reactions involving charged and uncharged molecules, respectively. N is Avogadro's number.

Fig. 1. Variation of observed rate constant with hydrogen ion concentration at 25° C

As:

$$\left(1 + \frac{T}{D} \frac{dD}{dT}\right) < 0$$

or aqueous solutions, $E^* > \text{or} < E$ depending on whether z_i and z_j are of unlike or like sign, respectively. For the system reported here $z_i z_j < 0$, and thus $E^* > E$. The preliminary results indicate that this may be so. This effect has been noted previously for $z_i z_j < 0$ (ref. 3) and $z_i z_j > 0$ (ref. 14). The present case, however, provides a much more direct test of effects of charges in so far as the two molecules being compared ($\text{NH}_2\text{CH}_2\text{COOEt}$, $\text{NH}_2\text{CH}_2\text{COOEt}$) differ, apart from charge, only in respect of the hydrogen. With substances investigated previously the comparison made was of the type $\text{SO}_3^-(\text{CH}_2)_n\text{COOEt}$ with $\text{CH}_3(\text{CH}_2)_n\text{COOEt}$.

From equation† (5) a value of R , 1.8 Å, is found assuming D to be the macroscopic dielectric constant. This can, in turn, be used to find $E^* - E$ equal to approximately 1.0 kcal mole⁻¹. Further refinements using a Kirkwood-Westheimer¹⁵-Tanford⁸ procedure indicate a value of approximately 1.6 kcal mole⁻¹ ($D_E = 14$, $R = 4.85$ Å).

The effect of charge on rate should be apparent in the pre-exponential terms. For reaction involving the charged species, formation of the transition state involves a decrease in net charge and thence an increase in entropy, due to release of water molecules of solvation on formation of the transition state. A less negative ΔS^\ddagger , relative to that for the uncharged species, is expected. This is tantamount to saying that there is an enhanced probability of reaction (relative to a neutral molecule-ion reaction) when two ions of opposite sign approach each other.

The alkaline hydrolysis of glycine esters has been examined previously, but no variation with pH has been noted. Bell and Coller¹⁶ investigated the hydrolysis over the pH range 9.70–11.55, but found no pH dependence. Other authors did not carry out the reaction at varying pH values. Reported values of the rate constant for the hydrolysis at 25°C are: (a) Bell and Coller¹⁶, 50.4 l.mole⁻¹ min⁻¹; (b) Gustafsson¹⁷, 36 l.mole⁻¹ min⁻¹; (c) White, Manning and Li², 44 l.mole⁻¹ min⁻¹; (d) Gelles and Robson¹⁸ (for methyl ester), 39 l.mole⁻¹ min⁻¹.

Conditions for values (b) and (c) are not reported, but from the experimental technique it seems safe to conclude that the pH was probably greater than 10. These data

† Values of the rate constants at infinite dilution were calculated, prior to substitution into equation (5).

are thus consistent with the present investigation and agree well with work^{2,8} on the methyl ester.

It can be seen that the effect of temperature on the overall observed rate, and on the gradient of the k_{obs}/V $[\text{H}^+]$, is complex; depending on the temperature coefficients of k , k^* and K_1 . Knowing these coefficients it is possible to predict that the pH dependence will be larger (and consequently more easy to measure) at temperatures $> 25^\circ\text{C}$, and work is in progress to extend the measurements.

Preliminary work has been carried out on the cupric ion catalysis. Titration curves for the ester in the presence of varying quantities of cupric ion suggest the presence of complexes such as CuE , CuE_2 .

Preliminary kinetic work shows that in addition to the hydroxide ion catalysed hydrolysis, a series of consecutive pseudo first-order reactions are occurring which can be initially interpreted as:

where CuG^+ is copper monoglycinate, and X is some, as yet, undetermined reactant. This is analogous to previous work¹⁸ where a maximum in the rate was obtained at pH 7–8 for k_1 , k_2 and k_3 .

I thank Dr. E. Gelles for suggesting this topic, and Dr. P. G. Wright for helpful discussion. This work was carried out during the tenure of the Edward A. Deeds junior fellowship of Queen's College, Dundee.

DIFFUSIVE TRANSPORT RATES IN STRUCTURED MEDIA

By PROF. A. B. METZNER

Department of Chemical Engineering, University of Delaware, Newark, Delaware

THE purpose of this short article is to call attention to the importance and potential applications of the abnormal diffusive transport rates recently observed in suspensions and in polymeric solutions and to offer a tentative interpretation of these phenomena.

The experimental results obtained for a variety of systems are given in Table 1; it is not the purpose of this article to present a complete review of all available data and additional results are given both in the references quoted in Table 1 and in other related papers^{1,2}. The important point to be made is that not infrequently the addition of either suspended solids or polymeric material to a homogeneous liquid increases the diffusive transport rates of some third species in this medium. This is not the case for all systems or at all concentration levels, but when it does occur the changes may be appreciable (up to 40 per cent in the case of the data of Table 1, and significantly larger effects have been noted³). Presumably,

even greater effects would be possible by optimizing the relevant factors involved, if these were understood, since the data given in Table 1 represent only measurements on systems chosen more or less at random rather than with the view of finding maximal effects of this kind. As the diffusivity increases are obtainable using either suspended solids or dissolved macromolecules, the total effects obtainable in biological media containing both kinds of constituents could conceivably be very appreciable and significantly affect the rates of respiratory and cellular ingestive processes of living organisms or the operability of machines designed to provide such functions. Thus the problem under discussion may be of interest in rather broad areas of biophysics and bioengineering as well as in polymer and colloid science.

Students of the diffusive behaviour of polymeric molecules in solution have observed or predicted effects which may have a common molecular origin, although, except

in the case of a small number of lucid publications⁴⁻⁶, the actual phenomenon has frequently been obscured by the dedicated devotion of the authors in this area of science to the reporting of phenomena in terms of empirical coefficients of obscure origin and value, as well as by the fact that the macromolecular transport rates are, at best, frequently quite low. The transport characteristics of systems in which the diffusivity increases with increasing concentration of the polymeric molecules involved have been shown to be closely related to the second virial coefficient of the solution and hence, among other variables, to the partial molal volume of the polymeric solute⁴⁻⁷. However, the extension of these considerations to make it possible to predict the behaviour of an ordinary (that is, not macromolecular) solute, in a polymer solution or a colloidal suspension, would appear to require additional considerations.

Such considerations appear to be embodied in a recent analysis of diffusion in liquids⁸ which enables the prediction of diffusivity in terms of the molecular geometry (size) of both the solute and the solvent constituents and the intermolecular force fields of each. If, as indicated by the high values of the second virial coefficient of the polymeric solutions of interest, the molecular 'packing' of the solvent molecules in the neighbourhood of a macromolecule is lower than in the bulk of the solution, a region of low resistance to mass transport will have been provided. In fact, since the term reflecting such decreased intermolecular packing appears in an exponential⁸, small changes in intermolecular spacing would be predicted to have major effects on the diffusivity. Similarly, in the case of diffusion in a slurry of colloidal particles, the intermolecular packing at the particle surface would be expected to be less than in the bulk of the fluid just from the usual geometric considerations of molecular packing at all planar surfaces. The visualization of the transport process therefore becomes one in which the addition of certain polymeric materials or colloidal solids to a continuous fluid may lead to the creation of a structured medium in which the packing of the fluid molecules in the immediate neighbourhood of the added macromolecule or particle is lower than in the continuum itself; these regions of low packing may represent regions of very high 'conductivity' for the diffusing species, depending in turn on their size and on the intermolecular force fields of the several species involved. The macromolecular or colloidal particles, of course, may also block the path of a diffusing species when the low-density 'short circuit' around the particles does not exist, as discussed elsewhere¹, and either mechanism could predominate, depending on

the molecular force fields involved. The magnitude of the diffusivity in a 'high conductivity' environment (the added species may in principle be predicted by extensions of the previous analysis of diffusion in liquids) although in practice several difficult steps remain to be overcome before the extension is a quantitative one.

The effect of regions of abnormally high or low diffusivity on the macroscopic diffusivity of the medium as a whole may be computed from the analogous analysis of conduction of electricity or heat in structured media⁹⁻¹², providing the distribution of these regions is random and the particle asymmetry may be considered adequately. A random distribution of these regions would appear to be reasonable in an undeformed fluid, but imposition of rapid rates of deformation of the fluid could be expected to lead to asymmetric mass transport properties. This problem has been investigated in steady laminar shearing flow fields over rather broad ranges of shear rate, using both suspensions and polymeric solutions, and no measurable effects have been found^{3,13}. The implications of this apparent inconsistency are not known at present.

Finally, it should be noted that the conductivity of the medium may become independent of that of the high-conductivity phases or regions if the ratio of conductances is sufficiently great¹¹ and, if this is presumed to be the case, some predictions of the diffusivity characteristics of the structured medium may be made without detailed knowledge of the actual diffusivity in the regions in the immediate neighbourhood of the dispersed matter.

In summary, it is seen that diffusive transport rates in liquids may be increased appreciably by creation of structured media through the solution of macromolecular species in the fluid or by the suspension of colloidal particles in it. Presumably, even much greater effects than those noted so far could be obtained by optimizing the relevant parameters. These effects would appear to have potentially important implications in those areas of physics and engineering involving biological or polymeric materials. A tentative hypothesis, which assumes the creation of a structured fluid medium having regions of high diffusivity in the immediate vicinity of the added particles or molecules, is advanced as a possible explanation of this phenomenon. Methods of developing this hypothesis, which proposes a mechanism analogous to that of conduction of heat or of electricity in disperse systems or of diffusion in crystalline solids¹⁴, are discussed.

This work has been supported by the National Science Foundation. I thank Prof. Astarita and Dr. Secor for letting me see their papers prior to publication, and Prof. Astarita for many stimulating discussions of the problem.

CONCENTRATION EFFECTS IN CHROMATOGRAPHIC ANALYSIS

By Prof. I. D. RATTEE, D. M. LEWIS and Dr. C. B. STEVENS

Department of Colour Chemistry, University of Leeds

DURING an investigation of the highly complex reaction of ω -chloroacetyl amino dyes with wool, thin-layer and paper chromatography have been widely used for the detection and identification of the reaction products. From time to time it was noticed that with the dyes used the R_F values, relative to one another, varied considerably, although the final order of separation with a given mixture using a particular solvent was the same. R_F values were observed to be dependent on the concentration of material initially loaded on to the paper. A number of workers have referred to such concentration effects. Åkerfeldt¹ found that the final area of the spot was directly proportional to the load of material applied. Fowler², using sucrose, found a linear relationship between the logarithm of the spot length and the logarithm of the load initially applied. He also observed that at low concentrations the plot of spot length against the logarithm of the load applied was linear. Fisher, Parsons and Morrison³, discussing quantitative paper chromatography, also found a linear relationship between spot length, or spot area, and the logarithm of the spot content when using certain amino acids and the sugars xylose and arabinose. Miyaki⁴ found that the logarithm of the difference between the initial and final lengths of the spot was a linear function of the concentration of material initially present in the spot. The effect we have observed is, however, not so much an increase in the length of the spot but a definite increase in R_F with increase in the load applied.

Giddings and Keller⁵ developed an equation relating a given number of molecules Nx in a spot, the distance moved, and the mean diffusion coefficient of the particular material in the support. We have sought to explain in rather different terms the concentration effects we have observed using an equation based on present-day theories of the adsorption of dyes by textile substrates.

It is considered that the effects arise from a Freundlich type of adsorption of the dyes by the support medium. The literature contains references to the desirability of avoiding the use of supports towards which the compounds under examination show strong substantivity, but no account seems to have been taken of the possibility of changes in the pattern of chromatographic behaviour arising from relatively weak substantivity effects.

If it is assumed that the distribution of substance between the eluent and the support obeys a Freundlich isotherm, and if D_F denotes the concentration of adsorbed material in equilibrium with D_S , the concentration of the substance in the eluant, then:

$$D_F = K_1 D_S^x$$

where K_1 is a constant and $x < 1$.

If it is further assumed that the velocity with which the substance under examination moves relative to the solvent front is proportional to the concentration not adsorbed, then:

$$R_F = K_2 D_S$$

Since the total concentration of the substance in the spot \bar{D} is equal to $D_F + D_S$, then:

$$\begin{aligned} \bar{D} - D_S &= K_1 D_S^x \\ &= \frac{K_1}{K_2^x} R_F^x \end{aligned}$$

and if $\bar{D} \gg D_S$, that is, quite a high degree of adsorption occurs, then:

$$\log \bar{D} = \log \frac{K_1}{K_2^x} + x \log R_F$$

Thus a linear relationship should exist between the logarithm of the R_F value and the logarithm of the load, if the substantivity for the support medium of the substance loaded is sufficiently high. The accuracy of this prediction will vary according to the scale of the error introduced by assuming $\bar{D} \gg D_S$. With the low solvent/support ratios obtained in chromatography this should, in fact, even hold with compounds which show only moderate substantivity to the particular support medium. Certainly using azo dyes of the type described here and paper as the support, \bar{D} will in most circumstances exceed D_S quite considerably.

Two orange dyes were used:

Mol. wt. 442

Mol. wt. 456

Chromatograms were run using 'Whatman 3MM' paper as support, *n*-butyl alcohol/acetic acid/water (4 : 2 : 1) as the eluant and enclosing the chromatogram in an all-glass Shandon tank, containing, in the bottom, sufficient eluent to saturate the atmosphere in the tank. All the runs were continued for 21 h at 20° C. For each dye spots of equal area were formed on the starting line. The distance between the starting point and the maximum concentration point of each spot was measured. An EEL densitometer was used to determine the maximum concentration points. Since the behaviour of both dyes at each concentration was determined at the same time under identical conditions, the distances moved were equivalent to the R_F values. The results are shown in Table 1.

Fig. 1 shows the plot of the logarithm of the distance against the logarithm of the load. In both cases the predicted linear relation was obtained up to an initial load of about 0.1200 mg.

Further evidence that substantivity plays a major part in determining the movement of the spots was obtained by examining the effect of different eluents. Using *n*-butyl alcohol/pyridine/water (1 : 1 : 1), under which conditions

Concentration of original dye solution (mg)	Distance (L) moved (cm)	
	Dye (i)	Dye (ii)
0.0125	16.80	16.10
0.0250	17.50	16.75
0.0375	18.20	17.20
0.0500	18.50	17.50
0.0625	19.40	17.80
0.0750	19.10	18.00
0.0875	19.60	18.20
0.1000	19.10	18.40
0.1125	19.80	18.40
0.1250	19.80	18.50
0.1375	19.75	18.50
0.1620	20.00	18.50
0.1750	20.10	18.60
0.1870	20.00	18.60

Fig. 1

hydrogen bonding of the dye to the substrate, and hence dye-substrate sensitivity, is reduced, the spots were far more compact, but the distances travelled were still dependent on concentration, though to a lesser extent.

The concentration of dye in the load has also been found to influence the chromatographic behaviour of mixtures of dyes:

Descending chromatograms were run for 21 h in *n*-butyl alcohol/acetic acid/water (4:1:2) under the same conditions as before. The dyes used in these experiments were:

Spots of equal area containing these dyes in different proportions were produced as follows:

- (1) [R.D.] constant
[H.D.] increasing (from right to left)

The resulting chromatogram is shown in Fig. 2.

It will be seen that the expected increased movement of dye H.D. with increasing concentration occurred. Dye R.D. behaved in exactly the same way even though it was applied in constant concentration. (Note: dye H.D. is the spot with the lower R_F value.)

- (2) [R.D.] increasing (right to left)
[H.D.] constant

The resulting chromatogram is shown in Fig. 3. In this case no obvious mixture effects were observed except that a slight retarding of the movement of dye R.D. is observed when this result is compared with that shown in Fig. 4 (a).

- (3) [R.D.] increasing (left to right)
[H.D.] increasing (right to left)

The resulting chromatogram is shown in Fig. 5. The position of the spots (on the extreme left) containing most dye H.D. and least dye R.D. shows that dye R.D. is held back. Particularly marked separation of the spot containing most dye R.D. and least dye H.D. occurred (on extreme right of Fig. 5).

It is obvious that the chromatographic behaviour of mixtures of dyes is affected by differences in the substantivity of each dye for the support. That this is the case with the adsorption of direct dyes on cellulose has

Fig. 2

Fig. 3

en shown by several workers. It has been observed at the equilibrium adsorption of a particular dye from solution containing a mixture of dyes is lower than from solution containing this dye alone (Boulton, Delph, Fothergill and Morton⁶; also Neale and Stringfellow⁷). Such behaviour is considered to be due to the following causes: (1) Competition between the different dye anions for the available surface sites. (2) The effect of each dye contributing to the surface charge on the fibre, and to the sodium ion concentration in it. (3) Interactions between the dyes in solutions.

In chromatography (1) is especially important since, under the conditions used, the support will be approaching saturation with dye. Applying all these factors to paper

Fig. 4

Fig. 5

chromatography, one would expect the behaviour of a dye in mixtures to differ from that when it alone is present, especially in the case of dyes which are substantive to the support. It would therefore appear to be important that this possibility should be taken into account, when using paper chromatography, in order to detect and separate dyes in mixtures.

GEOCHEMISTRY OF ANDESITES AND THE GROWTH OF CONTINENTS

By PROF. S. R. TAYLOR and DR. A. J. R. WHITE

Department of Geophysics and Geochemistry, and Department of Geology,
Australian National University, Canberra

THE growth of continents is one of the basic problems in geology. The rate of denudation is sufficient to erode continents to very low levels in periods brief ($10\text{--}50 \times 10^6$ years) compared with the extent of geological time¹. Accordingly, it is necessary to have a process by which material is added to the continents, not only to keep pace with the denudation, but also to allow for some growth. The chemical differences between continental crust and either oceanic crust or mantle demand that a chemical fractionation process operates as well as a simple addition of material.

Of the observable geological processes, basalt igneous activity is seen to add material from the mantle to the

crust in both oceanic and continental regions. Granitic rocks and their associates seem to be derived from within the deep crust. In orogenic regions eruption of andesitic lavas and ash is the dominant volcanic activity and adds material to the surface at rates of perhaps 1 km^3 per year². These orogenic zones are here interpreted as areas of active continental growth, as suggested by Wilson³.

The andesites possess the following properties:

(1) They appear to be restricted to orogenic belts and are absent from oceanic areas.

(2) They are the most voluminous eruptive rock in these belts. Other rocks have occasionally been referred to as andesites (Table 1) but are excluded from this study.

Table 1. NOMENCLATURE OF ANDESITES AND ANALOGOUS ROCKS

	Some past usages	Present nomenclature
Cale-alkaline volcanic series	Andesite	Andesite
Alkali volcanic series	Orogenic andesite	Hawaiite (ref. 3)
	Andesine andesite	Mugearite (ref. 3)
	Oligoclase basalt	Benmoreite (ref. 4)
	Trachyandesite (soda-rich)	Tristanite (ref. 4)
	Trachyandesite (potash-rich)	
Tholeiitic volcanic series	Andesite	
	Pigeonite andesite	Icelandite (ref. 5)
	Tholeiitic andesite	

They are developed in minor amounts in both continental and oceanic environments by fractional crystallization of basaltic magma³⁻⁵ and are different petrographically and chemically from the true andesites.

(3) There is a common, but not universal association of more silica-rich rhyolites, ignimbrites and dacites.

(4) True basalts are often absent, or present in minor amounts; only occasionally are they abundant (for example, Japan).

(5) The andesites frequently contain glass, are typically porphyritic and the plagioclase exhibits reverse and oscillatory zoning indicating non-equilibrium conditions during crystallization. Present data suggest that they are characterized by hypersthene in the groundmass.

(6) They are broadly uniform in composition, although commonly associated with minor more basic andesites, containing large crystals of olivine and pyroxene.

(7) Their composition bears a general resemblance to previous estimates of that of the continental crust.

In Table 2, the average composition is given of well-described andesites from New Zealand^{6,7}, Saipan⁸, California^{9,10} and Japan^{11,12}. Two recent estimates^{13,14} of the composition of the continental crust are also given. The average composition of the common igneous rocks, granite and basalt is also given. Fig. 1 shows a comparison of the composition of the continental crust, averages of granite and basalt, and the range in composition of andesites (filled rectangles). The unfilled rectangles represent the composition of rarer basic andesites, possibly resulting from accumulation of olivine and pyroxene crystals.

It is apparent from Table 2 and Fig. 1 that the composition of andesites bears a general resemblance to that of the continents. The major anomaly is the potassium content, which is too low by a factor of two. Possible explanations of this will be discussed later. Because of the importance of the andesites, a programme of geochemical research has been started, and determinations of major and trace elements, and Sr isotopes has been carried out on samples from New Zealand and Japan.

Fig. 1. Comparison of the major element composition of andesites, basalt, granite and continental crust. Filled rectangles, andesite; unfilled rectangles, basic andesite; x, basalt; —, continental crust

Work is planned on samples from New Guinea and Solomon Islands, Saipan in the Marianas arc, and Cascade Province in western United States, in order sample widely the circum-Pacific belt. Full details samples, analytical methods and individual determinations will be given elsewhere.

The major and trace element data already available permit some tentative conclusions to be drawn. Data for the strontium isotopes will be presented separately. The major elements were determined by conventional wet chemical methods, and the other elements by a combination of X-ray fluorescence, spectrochemical¹⁹ and source mass spectrographic²⁰ techniques.

The trace element data are shown in Fig. 2. Average basalt and granite abundances are shown, with the estimation for the continental crust, based on a 1:1 mix of acid and basic rocks. Although there is a general similarity between the andesite composition and that of this average the concentrations of many elements in andesites are lower than this crustal average. These include barium, rubidium, nickel, yttrium, lithium, thorium, caesium, uranium, tin and the rare earth elements. Except for nickel, these elements are all typically strongly concentrated upwards in the Earth since their large size, valency, makes it difficult for them to enter the principal crystal phases in the mantle^{21,22}. They are all typically concentrated in the last stages of fractionation, as resemble potassium among the major elements in this respect. K/Rb ratios for the common New Zealand andesites are 240, and 330 for the Japanese. The most basic andesites have ratios up to 340 for the New Zealand rocks, and 510 for the Japanese. The rare earth elements although apparently lower in absolute concentration show similar patterns to those of well-mixed crustal sediments, when normalized to lanthanum = 1.00. This shown in Fig. 3 for the odd-numbered rare earths.

The trace element data provide limitations to the various theories of origin of andesites. These theories fall into three main categories: (1) Fractionation of basic magma under oxidizing conditions. (2) Assimilation, contamination or mixing of acid and basic material. (3) Primary andesite magma developed by partial or complete melting of deep crustal or upper mantle material²³.

Volume relationships are generally not in favour of an origin by fractionation of basic magma. It is possible that the nickel content is too low for such an origin, but the trace element data do not exclude this possibility. The second alternative seems to be excluded by the present data. The low content (in andesites) of elements such as potassium, rubidium, uranium, thorium, rare earths, tin and lithium on the basis of any reasonable proportions of admixed granite rule out this mechanism. Preliminary results for strontium isotopic ratios support this conclusion²³.

Because of the serious limitations to the first process or geological grounds and to the second on geochemical arguments, the third process merits serious consideration. The relatively thin crust of about 30 km thickness present in typical orogenic areas²⁴ raises difficulties for an origin by fusion or partial fusion of deep crustal material. Temperatures to be expected at these depths are appropriate to the formation of granitic rocks²⁵, but may not be sufficient to form melts of andesitic composition. Experimental data bearing on this problem are lacking.

Table 2. AVERAGE COMPOSITIONS OF ANDESITE, CONTINENTAL CRUST AND COMMON ROCK TYPES

	Average andesite A (refs. 6-12)	Continental crust B (ref. 13)	C (ref. 14)	Average granite D (refs. 15-18)	Average basalt E (refs. 15, 17)
SiO ₂	60.1	59.4	60.3	71.2	48.9
Al ₂ O ₃	17.2	15.6	15.6	14.7	15.7
FeO	6.1	7.1	7.2	3.2	10.7
MgO	3.5	4.2	3.9	0.6	8.7
CaO	7.1	6.6	5.8	2.0	10.8
Na ₂ O	3.3	3.1	3.2	3.5	2.3
K ₂ O	1.3	2.3	2.5	4.2	0.7
TiO ₂	0.7	1.2	1.0	0.5	1.8

Fig. 2. Comparison of trace element composition of andesites, basalt, granite and continental crust. Filled rectangles, andesite; unfilled rectangles, basic andesite; O, granite; x, basalt; —, continental crust

zones is characterized by an anomalously low velocity region for compressional (P) waves. This is interpreted as a region of lower than normal density for the mantle²⁶ immediately beneath orogenic regions. There is thus a correlation between andesite volcanism and an anomalous low-density upper mantle. If andesites are derived from this low-density zone by partial melting, then they could make a major contribution to the growth of continents.

This hypothesis encounters the difficulty referred to earlier of a deficiency of potassium and related trace elements in andesites compared with present estimates of crustal composition. The following possibilities might explain this anomaly:

(1) Potassium and the related elements which are typically concentrated by fractionation processes might be overestimated in the continental crust. These elements could be concentrated in the upper and depleted in the lower crust so that sampling is overweighted in their favour. A lesser concentration of these elements in the crust would remove some difficulties for a chondritic Earth model²¹. Hence the composition of andesites may represent a more satisfactory overall average for the composition of the continental crust than previous estimates.

(2) The additional potassium, and other elements, could be provided by the acid volcanic rocks of rhyolitic composition commonly associated with andesites.

(3) Although we ourselves favour a philosophy based on the uniformitarian approach to geology²⁷, it is likely that the mantle has become depleted in potassium and related elements with time. Many of these elements should appear in the first products of partial melting. Thus recent andesites, studied here, could contain less of these elements than those of remote geological epochs. The composition of the continental crust would then represent the average of andesites erupted over a period of at least 3×10^9 years. Work is proceeding to test these several alternatives.

ASTROPHYSICS

Interstellar Obscuration

AN accurate extinction curve with a standard error of $\pm 0.008^m$ which has been derived for a region in the direction of Cygnus (looking along the spiral arm) from spectrophotometric observations at the Royal Observatory, Edinburgh¹, shows a pronounced discontinuity in slope at 4300 Å. This feature as well as recent rocket observations² rule out the possibility that the interstellar dust is made up of iron or ice particles. Hoyle and Wickramasinghe³ have suggested that graphite particles, formed on the surface of carbon stars, could be ejected into interstellar space by radiation pressure, and Wickramasinghe⁴ finds that such carbon particles may become covered with ice mantles. The wave-length 4300 Å is close to that at which the refractive index of graphite particles begins to change, the extinction of graphite being remarkably close to a $1/\lambda$ law in the region $0.8 \leq \lambda^{-1} \leq 2.3$ and thereafter deviating from such a law more or less according to particle size⁵. Nandy and Wickramasinghe⁶ have shown that the observed extinction curve for Cygnus can be well reproduced by the assumption of graphite cores with radii less than $\sim 0.06\mu$ covered with ice mantles.

Similar observations have been made at this Observatory in the direction of Perseus (across the spiral arm)⁷. The extinction curve for Perseus shows that the change of slope occurs at the same wave-length, 4300 Å, as found for Cygnus stars; but that the slope of the ultra-violet part of the extinction curve relative to the blue part decreases by 30 per cent as compared with that in Cygnus (Fig. 1). The Perseus curve can be well represented by a Gaussian distribution of graphite particles with a dispersion of $\pm 0.01\mu$ centred at 0.06μ (ref. 6).

The difference between the Cygnus and Perseus extinction laws could be explained if the interstellar matter were made up of particles covered with metallic impurities and aligned in a magnetic field⁸. The alignment properties of the particles would be different in Cygnus from those in Perseus because of the different angles of viewing, and the ratio of the slope of the ultra-violet part of the extinction curve to that in the blue would be expected to depend on the angle of viewing and the polarization of starlight per unit obscuration⁹. However, the work of Underhill and

Walker¹⁰, who examined the obscuration of stars in southern sky, and of Johnson¹¹ shows that the variation of the law of obscuration is not dependent on the angle of viewing.

More light can be thrown on this matter by examining the obscuration of the star HD 23512 in the young Pleiades cluster. This relatively nearby cluster is in the Cygnus arm and is embedded in nebulosity. The polarization per unit obscuration of the star HD 23512 is the same as the average value in Perseus and about four times that in Cygnus.

This star has now been examined both here and Mendoza¹². The Edinburgh results agree well with those of Mendoza (Fig. 2). The extinction curve of the Pleiades star is found to be almost the same as that for stars in the Cygnus region, but significantly different from that in Perseus.

Fig. 2. Pleiades extinction curve as compared with that for Cygnus. The vertical line denotes the uncertainty of the point. ●, Pleiades (Edinburgh); ○, Pleiades (Mendoza); ×, Cygnus

The theoretical model which fits the Cygnus curve gives the value of the ratio of total to selective absorptivity, $R = 3.1$. The extrapolation of infra-red measurements of Mendoza for the Pleiades star gives $R = 3.6$. An indirect measurement of R from measures of the line $H\gamma$ in the Pleiades stars gives $R = 3.1$ (ref. 13).

The extinction of the Pleiades star does not show any correlation of the slope of the ultra-violet part of the extinction curve relative to the blue part with the polarization per unit obscuration. The variation in the extinction law cannot be explained therefore by differences in the alignment of the particles.

The space distribution of stars observed for the examination of extinction is illustrated in Fig. 3, which shows schematically the three spiral arms of the Galaxy. It is of interest to note that the Cygnus extinction curve is representative of the majority of stars in the Cygnus arm. In the direction of Perseus, the spiral arm can be easily reached, and the stars situated in a small region in the Perseus arm exhibit an extinction law different from that in Cygnus. Whether or not the Perseus law is representative of the Perseus arm in general has yet to be investigated. Few data exist as yet for stars in the inner arm. The difference between the Cygnus and Perseus extinction laws can be explained if it is assumed that the extinction in Perseus is due to graphite grains only, and that in

The hatched lines represent the distribution of OB clusters, associations, and III regions, and crosses represent directions of new galactic longitude on a circle 6 kiloparsecs in diameter.

gnus to graphite cores with ice mantles. It appears therefore that there exists a regional variation in the composition of the interstellar dust particles which may be either a difference between the Cygnus and Perseus arm or a local variation within the Cygnus arm. The difference could be due to different physical conditions or to actual regional variations in chemical abundances. Further tests could come from the investigation of extinction in the Cassiopeia and Cepheus regions, which is now in progress here, and also from rocket observations.

I thank Mr. I. Nicolson and Mr. David Sugden for assistance with the reduction of the Pleiades plates.

New Limits to the Angular Sizes of Some Quasars

In previous experiments at Jodrell Bank the angular sizes of discrete radio sources have been investigated by means of long baseline interferometers^{1,2}. The highest resolving power used previously was obtained during observations at a wave-length $\lambda = 0.73$ m with telescopes 180,000 wave-lengths apart (134 km). Four quasi-stellar and one unidentified source were found to be unresolved in those observations. Their angular sizes

were thus shown to be smaller than 0.4 sec of arc. In a further attempt to resolve these sources another experiment has been carried out using the Mark I 250-ft. radio telescope at Jodrell Bank, and one of the 82-ft. radio telescopes operated by the Royal Radar Establishment, Malvern. The separation of these telescopes is 127 km, in a direction which is close to north-south. This interferometer worked on a wave-length $\lambda = 0.21$ m, so that the maximum resolving power was more than three times greater than had been obtained in the previous observations. The effective resolving power changes as sources are observed in different directions, but its maximum value is greater than 600,000 wave-lengths for most sources. With this baseline the output fringe frequency produced as the radio source moves through the lobes of the interferometer pattern varies with hour angle from 0 to as much as 40 c/s. An almost identical frequency was produced continuously by a digital 'fringe speed machine' and this was subtracted from the interferometer output, so that the fringe patterns displayed on the chart recorder were normally slower than 0.5 cycles/min. A microwave link system was established between the two observatories, via two repeater stations. A new very-high-frequency phase-locking system was also developed, with equipment at each site.

During these observations, the five sources which had not been resolved previously (3C 119, 286, 287, CTA 21 and 102) all gave clear fringe patterns over a wide range of hour angles, though for only one source did the amplitude remain approximately constant. These sources are listed in column 1 of Table 1. Column 2 shows their catalogued³ flux density, S , at $\lambda = 0.21$ m. The observed fringe amplitudes were normalized by daily observations of the source 3C 147, which was found to give clear fringe patterns at all hour angles. Corrections arising from various instrumental effects have been applied to these normalized values of fringe amplitude. It was found that when the sources were observed at elevations less than 15° these corrections were frequently greater than 20 per cent, and such observations have not been used. The corrected values of fringe amplitude have been calibrated by considering the maximum value observed for each source, which is shown in column 3 of Table 1. It was found that these maximum values are in an almost constant ratio to the total flux from each source, as shown in column 4, the mean value of these ratios being 14.1 ± 0.9 .

A constant ratio in column 4 would be obtained if the minimum linear dimensions of all these sources were similar, and they were at comparable distances, and were partially resolved to the same extent by effective baselines between $500,000\lambda$ and $600,000\lambda$. This is an improbable situation, and it seems more likely, as we assume, that each source was unresolved by the effective baseline at which the maximum value of fringe amplitude was

Table 1. RADIO SOURCES SMALLER THAN 0.1 SEC OF ARC IN AT LEAST ONE DIMENSION

Source	Flux S at $\lambda = 0.21$ m (flux units)*	Max. fringe amplitude, A , observed with tracking interferometer of aerial spacing 605,000 λ (arbitrary units)	A/S
3C 119	3.5 ± 0.8	125 ± 10	14.7 ± 1.8
3C 286	15.1 ± 0.4	245 ± 20	15.2 ± 1.5
3C 287	7.6 ± 1.5	95 ± 5	12.5 ± 2.5

CTA 102	1.037			
3C 287	1.055			
3C 9	2.012			

* These linear dimensions have been calculated for model universes (ref. 4) in which the acceleration parameter $q_0 = +1$. If $q_0 = 0$, these values must be multiplied by a factor $(1 + 0.5z)$ which for these sources lies in the range 1.2–2.01.

† Results (ref. 7) of detailed analysis of observations at $\lambda = 0.73$ m.

‡ None of the available evidence suggests that the source contains fine structure within this elliptical component, but further analyses or observations even higher resolution could conceivably reveal a more complex structure, within these overall dimensions, as in the case of 3C 273B.

§ Fringe patterns corresponding to partial resolution of this source were recorded during the observations at $\lambda = 0.21$ m described above. They have not yet been analysed in sufficient detail to improve significantly the earlier interpretation of the angular structure of this source.

¶ A weak source at $\lambda = 0.73$ and $\lambda = 0.21$ m. Even if it were unresolved, the signal-to-noise ratio would be poor under optimum conditions, and the fringe pattern might not have been recognized during those observations which were attempted.

observed. This means that each of these sources is smaller than 0.1 sec of arc in at least one direction. The source CTA 102 did not appear to be resolved at any hour angle when its elevation was greater than 15° , so that its angular size is shown to be less than 0.1 sec of arc in all position angles. Each of the other sources was partially resolved at some hour angle, and the corresponding maximum angular dimensions (assuming gaussian source models) were in the range 0.12–0.16 sec of arc, as shown in column 5 of Table 1.

The quasar 3C 273 was also observed and was found to give clear fringe patterns of unexpectedly large amplitude with one well-marked minimum near meridian transit. Observations of lunar occultations of this source show that it consists of two components, A and B, the centres of which are 19.5 sec apart in position angle 044° . If both these components had contributed to the fringe patterns observed at this baseline, a pronounced minimum would have been observed every 10–15 min at most hour angles. As these frequent minima were not observed, it follows that only one component of the source is small enough to give fringe patterns at this baseline, and that it, in turn, probably consists of two parts, which are each smaller than 0.1 sec of arc.

As only one minimum was observed, the angular separation of these parts and the position angle cannot, by inspection, be determined uniquely, though they may be obtained in due course by more detailed analyses. If it is assumed that this position angle is also 044° , the separation is of the order 0.4 sec of arc.

This interpretation of our observations, when calibrated with the factor derived from the sources discussed earlier, shows that the two parts of one component of 3C 273 are now giving a flux density not less than 30 ± 2 flux units. As may be seen in Table 2, this is significantly greater than the value of 23.3 flux units derived for the brighter component, B, from the ratio given by the occultation observations of 1962-9. The total flux from this source was therefore re-measured recently, with the Mark I telescope at Jodrell Bank, and compared with the radio galaxies 3C 348 and 353. These measurements show

increased. This conclusion may be compared with the measurements reported by Dent³ which show that a 8,000 Mc/s, where almost all the radiation comes from component B, the flux has increased by 40 per cent in 2.5 years.

We have summarized in Table 3 our current interpretations, based on these and earlier measurements, of the angular dimensions of the ten quasi-stellar sources the redshifts of which have been published^{1,2}. Possible values of the linear dimensions of the radio-emitting regions of these sources are shown in columns 4 and 5. Those in column 4 have been calculated on the hypothesis that the redshifts of these sources arise from the general expansion of the Universe, and so correspond to distances greater than 600 Mpc. The values given in column 5 are calculated on the hypothesis suggested by Hoyle and Burbidge⁶, that the emitting regions are at distances of order 10 Mpc, and their redshifts arise from very high intrinsic velocities of recession of the individual objects

RADIOPHYSICS

Scintillations on the Small Diameter Radio Sources

IRREGULARITIES in the solar wind appear to be responsible for the rapid scintillations on the radiation from small diameter radio sources¹, and for some of the fine structure of Jovian decametric bursts². At the Arecibo Ionospheric Observatory the irregularities as well as the sources are being examined by their scintillations. Early results of this programme have been reported by Cohen and Drake³. The purpose of this communication is merely to report that the scintillation phenomenon has been seen over an extended range of frequencies and positions, and that it is very strong and persistent.

Mc/s records of 3C-298 and 3C-317, taken on May 22, 1965, when 3C-298 was about 11 h east of the Sun. The two sources have approximately the same strength, as shown by the records; 3C-298 scintillates, but 3C-317 does not. The effect of scintillations shows up strongly in Figs. 2 and 3. Fig. 2 shows the unnormalized autocorrelation functions obtained from 5-min samples of the records, sampled 10 times per sec. The 3C-317 autocorrelation function has essentially the same strength and shape as those functions obtained when tracking the cold sky; it is an exponential with e^{-1} width equal to the output time constant of the radiometer. The autocorrelation function at zero lag is proportional to the variance of the fluctuating output signal, and so the root mean square fluctuation level for 3C-298 is twice that which would have been expected in the absence of scintillations. The scintillation index for 3C-298 is 0.041. (Index is defined as excess root mean square fluctuations divided by antenna temperature.)

Fig. 3 shows the power spectra of the radiometer output signals, obtained by computing the approximate Fourier transforms of the autocorrelation functions. The 3C-298 spectrum has excess energy only at low frequencies. This excess is the scintillation spectrum; it is roughly gaussian in shape, with an e^{-1} width of 0.55 ± 0.05 c/s. The peaks at 3.3 c/s are apparently due to aliasing.

A short radiometer time constant is required for scintillation observations, since the fluctuations may have periods of 1 sec or less. This results in a poor signal-to-

Fig. 1. 195 Mc/s records of 3C-298 and 3C-317, May 22, 1965. Successive on-off records are shown. Time constant 0.1

The scintillations are very strong when the source is very narrow and close to the Sun. For example, on May 23, 1965, CTA-21 was about 11° from the Sun. At 430 Mc/s the scintillations were very strong, with minima about 0.2 the mean value. As another example, on June 13, 1965, 3C-138 was about 7° from the Sun. Strong scintillations were observed on 195, 430 and 611 Mc/s. On all these frequencies the minima were about half the mean value. These observations were made with the 1,000-ft. spherical reflector, using point feeds giving beam-widths of 33', 16' and 14' at 195, 430 and 611 Mc/s, respectively. Small diameter sources, such as CTA-21 and 3C-138 (ref. 4), can readily be found by their very strong scintillations, if they are close to the Sun.

The very narrow sources, furthermore, always scintillate, even when they are far from the Sun. Fig. 1 shows 195

Fig. 3. Power spectra (in arbitrary units) for 3C-298 (scintillating) and 3C-317 (non-scintillating)

Fig. 2. Autocorrelation functions (in arbitrary units) for 3C-298 (scintillating) and 3C-317 (non-scintillating). Samples were taken 10 times per sec for 5 min; 90 lags are shown

noise ratio for weak sources. Digital processing, however, can greatly increase the visibility of the scintillations.

I thank E. E. Salpeter for his advice, and Mrs. N. Earle and Mrs. S. Jack for assistance with the calculations. The Arecibo Ionospheric Observatory is operated by Cornell University with the support of the Advanced Research Projects Agency under a research contract with the Air Force Office of Scientific Research.

PHYSICS

Combined Very High Pressure/High Temperature Calibration of the Tetrahedral Anvil Apparatus, Fusion Curves of Zinc, Aluminium, Germanium and Silicon to 60 kilobars

In apparatus of the tetrahedral anvil or of the 'belt' type¹, where a solid-pressure transmitting medium such as pyrophyllite is used, the relation between load and pressure is fairly complicated². The pressure calibration at room temperature is frequently made in terms of the usual resistance transitions in bismuth, thallium and barium¹. There is no guarantee that such a calibration will be valid for the high-temperature range up to more than 1,000° C in which such apparatus is often used.

To check on this point, the tetrahedral anvil apparatus has been used to determine the melting points of zinc, aluminium, germanium and silicon as a function of the pressure inferred from a room temperature calibration. These results can then be compared with previous determinations³⁻⁶ using piston and cylinder apparatus for which the temperature dependence of the load versus pressure calibration would be expected to be relatively small.

The NBS-type tetrahedral anvil apparatus used had 1.90-cm edge cemented (6 per cent cobalt) carbide anvils, and the 2.38-cm edge tetrahedra were made from pyrophyllite ('Alsil' grade). The experimental arrangement is shown in Fig. 1; the two alternative thermocouple positions shown gave identical results. The thermocouples used were chromel/alumel, and were of the sheathed 'Thermocoax' type with a sheath diameter of 0.5 mm: these were carried directly into the tetrahedron through an edge. No correction was applied for the effect of pressure on the thermal e.m.f. Melting was detected by simple thermal analysis, with the thermal e.m.f. displayed against a constant time base on a fast-acting XY recorder, since the cooling rate of the tetrahedral apparatus is rapid (400°/sec from 1,000° C).

The materials used in these experiments were 99.99 per cent pure or better and, to minimize possible contamination of the sample by its container, the following procedure was adopted. At a given anvil load, temperature was first raised slowly to ~0.7 of the expected melting point. Temperature was then increased rapidly (using the fast thermal response of the apparatus) by switching a suitable resistance from the primary of the heater power supply transformer. When melting was indicated by the appropriate 'arrest' on the rise curve, the heater supply was disconnected and the cooling curve taken. This ensured that the sample was heated in contact with its

Fig. 1. Cooling curve of zinc specimen cooled from 720° C at 32 kbar, showing 'arrest' due to freezing. Inset shows tetrahedron arrangement

Fig. 2. Fusion temperatures as a function of pressure. (a) Zinc and aluminium: (b) germanium and silicon. \circ , ref. 3; +, refs. 4 and 5; \times , ref. 6; \bigcirc , present work, pressures inferred from room temperature calibration

surroundings for a few seconds only, and X-ray microprobe analysis of selected specimens confirmed that no significant contamination had occurred during the heating cycle for any of the materials in tantalum containers. In view of previous experience³, suggesting that molybdenum is a suitable container for aluminium, it is interesting to note that we have found evidence of considerable reaction between these metals at high pressures, especially at temperatures approaching 1,000° C, where depression of the freezing point by as much as 50° C have been observed. X-ray microprobe analysis confirmed that a reaction had occurred in these cases with the formation of an intermetallic compound, probably MoAl_2 .

A typical arrest corresponding to solidification for a zinc specimen cooled from 730° C is shown in Fig. 1. In general, well-defined 'arrests' of this type were obtained during these experiments, and there was no evidence of supercooling despite the high cooling rates. Quite frequently 'arrests' began with a region of finite slope rather than an accurate horizontal; in these cases the point of inflexion was taken to indicate freezing. The maximum error of measurement in these experiments is about $\pm 5^\circ \text{C}$.

Fig. 2 shows the fusion curves to 60 kbar, pressures being inferred from a subsidiary room pressure calibration with a similarly sized test sample. All measurements were made during the loading cycle and the repeatability of pressures is in the range ± 1.5 kbar. These results are compared with two previous investigations: (1) Butuzov³ used relatively large samples pressurized either in argon or pentane so that truly hydrostatic conditions were obtained. Melting temperature was determined by differential thermal analysis, and pressures by a manganin gauge with an accuracy of 0.1 kbar. (2) Using piston and cylinder apparatus with tale as the pressure-transmitting medium, Kennedy and Newton⁴ have determined the fusion curve of zinc, Jayaraman, Klement, Newton and Kennedy⁵ that of

minium, and Jayaraman, Klement and Kennedy⁶ that germanium and of silicon. Pressure was inferred from force and area, with a correction for piston friction, giving an accuracy of 1.0 kbar.

Fig. 2 shows a very satisfactory agreement between the curves obtained in the present work and a linear extrapolation of those of Butuzov³ for zinc and aluminium: that, in the range up to 60 kbar and 1,100° C, a reasonable agreement is also obtained with the curves obtained in refs. 4 and 6 for zinc, silicon and germanium. Considering that the various determinations were made in widely differing types of apparatus, and in particular that Butuzov's conditions were truly hydrostatic, it is a reasonable conclusion that the effect of temperature on the dP/pressure calibration curve for the tetrahedral apparatus is small, certainly less than ± 3 kbar at 50 kbar and 1,100° C.

There is a significant difference, amounting to 8 kbar (50° C) at 40 kbar and 900° C, between the present results for aluminium and those of ref. 5. It is possible that at least some of this effect is due to the reaction discussed above between molten aluminium and the molybdenum containers used in the latter work.

In a recent determination of the phase diagrams of silicon and germanium, Bundy⁷ used a modified 'belt' type apparatus to produce pressures up to about 200 kbar and 1,000° C. With this apparatus a large pressure rise due to adiabatic heating at the specimen was inferred, which was roughly proportional to the product of the initial pressure and the temperature rise, and would amount to about 3 kbar at 50 kbar and 1,000° C. The compatibility of the present results with those of other workers implies that such a large effect is not encountered with the tetrahedral apparatus as used in this work.

We thank Miss A. Thake, who carried out many of the experiments, and L. Hailes for the microprobe analysis of specimens; we also thank C. H. L. Goodman for discussion.

A New Absolute Determination of the Acceleration due to Gravity at the National Physical Laboratory

An absolute determination of the acceleration due to gravity at a site in the National Physical Laboratory has recently been completed. It is the first to be made by timing the symmetrical up-and-down motion of a body moving freely under gravity, and the uncertainty of the result is considerably less than that of any previous measurement.

If a body is timed as it crosses two horizontal planes with a vertical separation H , and if the time interval between crossings of the lower plane is T_1 and of the upper plane T_2 , then:

$$g = \frac{8H}{T_1^2 - T_2^2}$$

A correction has to be applied for the decrease of gravity with height.

In the present experiment the planes were defined optically by pairs of horizontal slits and the moving object was a glass ball which focused one slit of a pair on the other when it was symmetrically between them. One

slit was illuminated and a photomultiplier behind the other recorded the flash of light as the ball passed. The pairs of slits were incorporated in composite blocks of fused silica, the vertical distance (1 m) between the blocks at the upper and lower positions being measured by means of an interferometer.

The advantages of this method have been discussed recently¹ and it is sufficient to say that they have been fully borne out; in particular the measured acceleration is independent of air resistance.

The measured value of gravity, reduced to the British Fundamental Station in the National Physical Laboratory², is 981 181.77 mgal, with a standard deviation of 0.13 mgal (1 mgal = 10^{-3} m/sec²).

The uncertainty comes mainly from microseismic disturbances. An earlier determination at the National Physical Laboratory with a reversible pendulum³ gave a value of 981 183.2, s.d. 0.7 mgal at the British Fundamental Station. The difference of 1.4 mgal from the new result is just twice the standard deviation of Clark's value. Comparisons with other determinations will be discussed in the full account of the measurements which will be published later.

Deformation of Gas Bubbles and Liquid Drops in an Electrically Stressed Insulating Liquid

THE recent paper by Garton and Krasucki¹ is of considerable interest and reminded me of some of the work I undertook about five years ago². I observed a similar phenomenon under different conditions. This brief note is to bring to notice some of my results obtained at that time, which serve as further evidence that gas bubbles and liquid drops always tend to elongate in the direction of the applied field in an insulating liquid, irrespective of whether the permittivity of the bubble or drop is larger or smaller than that of the surrounding liquid.

A glass test cell 5 in. \times 3 in. \times 2 in. was used, containing a pair of parallel brass plane electrodes of size 4 in. \times 2 in. with a separation of 0.5 in. aligned horizontally. The test cell was fully filled with transformer oil, and an air bubble or a water drop could be introduced into the cell through two small holes in the top and the bottom of the cell. The pressure on the liquid was kept at atmospheric pressure and the temperature 20° C. The air bubble was injected through the bottom hole and it moved up through the centre of the liquid gap by buoyancy force, while the water drop was injected through the top hole and it moved down through the centre of the liquid gap by gravitation force. The 50-c/s a.c. field was first applied and a photograph was taken when the bubble reached the centre of the liquid gap. This method was different from that adopted by Garton and Krasucki, who deliberately eliminated the buoyancy force by rotating the test cell to maintain the bubble in a fixed position. However, their results and mine agree qualitatively. Fig. 1 shows an air bubble elongated at 22.5 kV and 28.5 kV though they were slightly distorted. Fig. 2 shows a water drop elongated and a large drop bursting into many droplets at 6 kV. The bubbles and drops in (a), (b) and (c) of Figs. 1 and 2 were not originally identical in size, since the device could not control their sizes accurately. But it can be seen that the greater the difference in permittivity between the bubble (or drop) and the insulating liquid, and the larger the original size of the bubble (or drop), the smaller is the electrical field required to cause elongation—as predicted by theory^{1,2}.

Fig. 1. An air-bubble elongated in the direction of the applied field in transformer oil. The 50-c/s a.c. voltage (root mean square) across a liquid gap of 0.5 in.: (a) $V=0$; (b) $V=22.5$ kV; (c) $V=28.5$ kV

Fig. 2. A water drop elongated in the direction of the applied field in transformer oil. The 50-c/s a.c. voltage (root mean square) across a liquid gap of 0.5 in.: (a) $V=0$; (b) $V=6$ kV; (c) burst of a large water drop at $V=6$ kV

It should be noted that the experimental conditions were somewhat different from the assumed conditions on which the theory was based. For example, the bubble size under experimental investigation was not so small compared with the liquid gap that the charge distribution on the electrodes before and after the introduction of a bubble was identical with the case for a field of fixed source distribution. This point must be borne in mind when comparing experimental results with theory. Furthermore, free charges inside or outside the bubble may also influence the deformation. Allan and Mason³ have reported that under certain conditions the fluid drops were flattened into oblate spheroids in the field. This phenomenon may possibly be due to the attractive force between positive and negative charges accumulated on the bubble surface, which, so far, has been ignored in the theory. More work, both theoretical and experimental, is necessary in order to clarify many points which are still not understood.

GEOPHYSICS

Variation according to Latitude of the Electron Content of the Ionosphere near the Auroral Zone

SOME evidence has been obtained from single-frequency Faraday measurements using the satellite 1963-49C, reported by Lyszka and Taylor¹, that the sub-satellite electron content, n_t , of the ionosphere at high latitudes may consist of two components. The first component, which decreases gradually with increasing latitude, is probably produced by ultra-violet radiation from the Sun; the second, irregular, component seems to dominate at latitudes greater than 65° N. It was suggested that the latter could either be produced by low-energy corpuscular radiation, or that it could be a manifestation of transport processes. Some more accurate measurements of the electron content at high latitudes, obtained from differential Faraday observations of the multifrequency beacon satellite S-66 (1964-64A), now show that the first explanation of the irregular component seems more plausible.

The electron contents have been calculated using data from 40 and 41 Mc/s records of S-66 made at Kiruna, Sweden (67.8° N., 20.4° E.), during the first two months of the satellite's life. The method was the same as that used for the reduction of two-frequency Moon radar data; n_t was calculated at each Faraday null time and plotted as a function of sub-ionospheric geocentric latitude. Some of the resulting curves are shown in Figs. 1 and 2 and those corresponding to a time of day shortly before local noon are given in Fig. 1 and those to a time shortly after local midnight in Fig. 2. All these results refer to the second half of November 1964. It can be seen that near noon n_t decreases with latitude; small irregularities often occur at latitudes of about 65° N. Night-time curves, particularly those from 03-04 local time, show a gradual decrease of n_t up to about 60° N., followed by an increase up to values at least as great as those observed at 50° N.

It may also be noted that the electron contents shown here are, on average, lower than those obtained from single-frequency records by assuming the effective thickness of ionosphere to be 350 km (ref. 1). Equivalent slab thicknesses were calculated using simultaneous values of maximum electron density, N_{\max} , obtained from the equation:

$$N_{\max}(\text{e/cm}^3) = 1.24 \times 10^4 (f_o F2)^2$$

where $f_o F2$ is the ordinary wave critical frequency in Mc/s. For this purpose $f_o F2$ values from six Scandinavian stations, covering an interval of 10 degrees of latitude were used. The results show that at high latitudes the effective thickness is much less than 350 km during the daytime, and sometimes less than 200 km. However, when the second component of n_t was present, effective thicknesses a few times larger than 350 km were obtained. As an example, effective thicknesses obtained for one of the transits shown in Fig. 2, transit No. 658, are given in Table 1 (Nov. 27, 1964, 0200 local time).

Table 1

Station	Geographic latitude ($^\circ$ N.)	$f_o F2$ (Mc/s)	Effective thickness (km)
Sodankylä	67.4	2.0	650
Lycksele	64.7	1.9	413
Uppsala	59.8	2.0	222

An examination of $f_o F2$ values shows that in many cases during the night-time, N_{\max} changes with latitude in the same way as n_t , that is, it shows a definite minimum value. As an example, N_{\max} values from 03 to 04 local time of November 22 are shown in Fig. 3. This phenomenon may also be found during the early morning hours on averaged world contours of $f_o F2$ published by Martyn².

Any transport of ionization is almost certainly directed along the magnetic field lines, that is, nearly vertically, and it seems unlikely that the large increase of the

Fig. 1. Electron contents for a number of satellite transits shortly before local noon during the second half of November 1964 plotted as a function of geocentric latitude.

Fig. 2. Electron contents for a number of satellite transits shortly after local midnight during the second half of November 1964 plotted as a function of geocentric latitude

Fig. 3. Electron densities at the maximum of the F-layer, N_{max} , from 03 (O) to 04 (●) local time on November 22, 1964, plotted as a function of the geographic latitudes of the ionosonde stations

electron content up to the satellite altitude (1,000 km) can be due to this cause. It would mean that there are at least as many electrons above 1,000 km as below; electrons which can, moreover, in certain conditions move downwards. There is at present no evidence for the existence of such a reservoir of ionization in the upper F-region, though there are few relevant high-latitude observations. Thus it seems more reasonable to attribute the increase of n_e to low energy corpuscular radiation, possibly electrons, producing additional ionization in the ionosphere at auroral latitudes. Their energy must be less than 1 keV since electrons with higher energy reach altitudes below 180 km without ionizing the F-layer⁴.

Further investigation of electron contents at auroral latitudes is needed before any definite conclusions can be drawn. It is already clear that the S-66 satellite is an excellent instrument in this type of investigation.

GEOLOGY

Holothurian Sclerites from the Speeton Clay

DURING an examination of the Foraminifera from the Lower Cretaceous clays of Speeton, Yorkshire, a number of samples were found to contain holothurian sclerites. This was an unexpected occurrence, as Frizzell and Exline¹

have pointed out that virtually no work has been published on sclerites from strata of Cretaceous age. The only previous records of Cretaceous holothurian sclerites are *Calchigula* (?) *huckei* from the Gault of Pomerania, *Theelia rotula* (Egger) from Germany and *Hemisphaeranthos franki* (Müller) from the Turonian of Germany. 'Chirodota' from the Hauterivian of France were noted by Deprat², and Wetzel³ obtained sclerites from a Baltic flint which Deflandre-Rigaud⁴ identified as *Myriotrochites elegans* (Schlumberger), *Chiridotites atavus* (Waagen) and *Chiridotites cf. ingens* (Joshua). More recently Kemper⁵ recorded 'Holothurienreste' from the Hauterivian of Germany, though he did not describe them.

A systematic search for holothurian spicules in more than two hundred micropalaeontological residues of the Speeton clay, mainly from the type locality but also from borehole material, revealed several horizons which contained a large number of holothurian remains. All were obtained from strata of Hauterivian and Barremian age.

The sclerites from Speeton belong to four families, Achistridae, Theeliidae, Stichopitidae and Priscopedatidae; all are well preserved and free from matrix and secondary growth. Of particular interest in the Barremian clays is the occurrence of the Family Achistridae, which is represented by the species *Achistrum* (*Cancellrum*) *monochordata* Hodson, Harris and Lawson. This is a sclerite in the form of a hook, with a terminal loop which is crossed by a single cross-bar. Forty-one examples of this species have so far been found. With this record of *Achistrum* (*Cancellrum*) *monochordata* the range of the Family Achistridae, previously regarded as being from the Devonian (?) to the Jurassic, can now be extended to include the Lower Cretaceous.

It is interesting to note that *A. monochordata* is a common form species in the Oxfordian^{6,7}, though the specimens from the Barremian are generally smaller than those from the Jurassic. The widths of the terminal loop in the specimens from Speeton range from 0.090 mm to 0.144 mm, while those from the Oxfordian range from 0.162 mm to 0.324 mm.

So far as I am aware, holothurian sclerites have not previously been recorded from the Cretaceous of Britain.

CHEMISTRY

Polyamide Layer Chromatography of DNP Amino-acids

METHODS for the identification of DNP amino-acids by paper or thin-layer chromatography were used to determine the N-terminal group in polypeptide structures. Recent developments in silica-gel thin-layer chromatography have made possible the rapid identification of amino-acids in biological mixtures¹.

The separation of various DNP amino-acids on a polyamide column was developed by Steuerle and Hille² and by Grassmann *et al.*³, but no practical method for separating micro samples by polyamide thin-layer chromatography has been developed.

The polyamide layer (Chen-Hsin-Tang Chemicals Co., No. 75, Section I, HanKou St., Taipei, Taiwan), according to Wang⁴, gave better results and durable polyamide layer. We have applied this polyamide layer to several

A, *n*-Butanol-acetic acid (9 : 1); B, 2-butanone-chloroform-formic acid (3 : 7 : 1); C, ethanol-water (63 : 37); D, dimethylformamide-acetic acid-water-ethanol (5 : 10 : 30 : 20); E, methanol-formic acid (9 : 1).

DNP amino-acids. Five solvent systems: solvent A, *n*-butanol-acetic acid (9 : 1); B, 2-butanone-chloroform-formic acid (3 : 7 : 1); C, ethanol-water (63 : 37); D, dimethylformamide-acetic acid-water-ethanol (5 : 10 : 30 : 20); E, methanol-formic acid (9 : 1), were excellent for one-dimension chromatography. The R_F values and the time required for plate development are shown in Table 1, and Fig. 1a shows a typical ultra-violet contact photograph of these chromatograms.

Fig. 1. Plate: 15 cm \times 15 cm; solvent system: 2-butanone- CHCl_3 - HCOOH (3 : 7 : 1) 13 cm. Key: 1, DNP-Isoleu; 2, DNP-Thr; 3, bis-DNP-Lys; 4, DNP-DL-Val; 5, bis-DNP-His; 6, DNP-Ala; 7, DNP-DL-Met; 8, DNP-H-Asp; 9, DNP-DL-Leu; 10, DNP-DL-Ser; 11, ϵ -DNP-Lys-HCl

In both solvent systems C and D, the times required for development are faster than solvent system A, but some of the DNP amino-acids give tailing spots. Solvent B exhibits a completely different tendency in R_F values. The similar effect of chlorinated hydrocarbon was also observed in phenols⁴. The solvent system D is the same as that used by Grassmann *et al.*³ for column chromatography.

Fig. 2. Plate: 15 cm \times 15 cm; solvent system: first, BuOH-AcOH (9 : 1) 12 cm; second, 2-butanone- CHCl_3 - HCOOH (3 : 7 : 1) 13 cm. Key: 1, ϵ -DNP-Lys-HCl; 2, bis-DNP-His; 3, DNP-H-Asp; 4, DNP-DL-Ser; 5, DNP-Thr; 6, DNP-Ala; 7, DNP-DL-Met; 8, bis-DNP-Lys; 9, DNP-DL-Val; 10, DNP-Isoleu; 11, DNP-DL-Leu

The combination of solvent systems A and B in two-dimensional development was also tried. This is shown in Fig. 2a and b. Leucine and isoleucine cannot be separated clearly by these systems because these two are too closely related in structure.

The polyamide layer gives less diffused spots and better separation than silica-gel thin-layer chromatography.

This durable polyamide layer with high resolution might be a promising method for the identification of DNP amino-acids.

Distribution of Plutonium in Serum Proteins following Intravenous Injection into Rats

PREVIOUS workers have shown that sera of various mammals are capable of binding plutonium. Hunts and Barron¹ prepared serum from dogs which had been intravenously injected with a hexavalent plutonium citrate complex. Electrophoresis of the serum in a Tiselius type of apparatus showed that the β -globulin fraction combines with the plutonium. Beliaev², using paper electrophoretic methods, showed that plutonium is bound principally to the globulin fractions. The serum used in this latter piece of work was obtained from rats 24 h after intraperitoneal injection of a tetravalent plutonium citrate complex. The results obtained by Beliaev were not very reproducible, due possibly to buffer salt interactions and the influence of the electric field. Accordingly we have measured the distribution of intravenously injected tetravalent plutonium in the blood serum of the rat. The results presented here show that in blood obtained from the rat within 0.5 h of injection, the plutonium is bound to the transferrin proteins.

The serum used for this work was prepared by Dr. D. M. Taylor of the Institute of Cancer Research, Sutton, Surrey. The plutonium stock was $\text{Pu}(\text{NO}_3)_4$ in nitric acid. Immediately before injection of about 0.1 $\mu\text{c.}$, the sample was diluted with water. The elapsed time between dilution of the sample and its injection into the rat was short. Consequently the principal plutonium species injected into the rat was the tetravalent one. The rat was killed within 30 min of the injection. The blood was allowed to clot at room temperature for 2 h, stood overnight at 4°C, and then centrifuged. The supernate was stored at -20°C until required.

The blood proteins were separated into three fractions by the relatively mild method of gel-filtration, and further resolved by ion exchange as described by Gelotte, Flodin and Killander³. The distribution of the serum proteins in the eluates was determined spectrophotometrically at 254 m μ . The relative plutonium content of protein samples was determined by counting the delayed neutron emission following neutron irradiation. Delayed neutron emission induced by thermal neutron irradiation of fissile nuclides is a highly specific property, and has been used by Amiel⁴ as an analytical method for the determination of uranium-235. The plutonium supplied by the Radiochemical Centre, Amersham, is free from other fissile elements, hence Amiel's method was used as a simple and rapid method of analysis.

Plutonium was found to be present in the albumin/transferrin fraction only, following protein resolution by

Fig. 1. Chromatography of the transferrin/albumin fraction on a column of DEAE-Sephadex A-50¹. Elution was started with 0.1 M 2-amino-2-hydroxymethylpropane 1:3 diol (*tris*) and its hydrochloride in 0.1 M sodium chloride, pH 8.0, followed by a gradient of 0.1 M–2.0 M NaCl in 0.1 M *tris*-HCl. The fraction volumes were about 3.5 ml. —, Transmission; ----, radioactivity

Sephadex G-200² gel-filtration. Resolution of the albumin/transferrin fraction into its components by DEAE-Sephadex A-50¹ and subsequent delayed neutron counting showed plutonium to be present in the transferrin fraction only as depicted in Fig. 1. Additionally the protein fractions were characterized by electrophoresis on cellulose acetate strips, using veronal buffer at pH 8.6 and staining with Ponceau S (ref. 5). Autoradiography of the unstained electrophoresis strips demonstrated that the plutonium migrates at the same rate as the transferrin.

Far-infra-red Spectra of some Square-planar Ions

THERE are three different assignments of the infra-red-active modes of K_2PtCl_4 in the literature¹⁻³. One was based on a low-resolution spectrum¹ and is thus misleading. The other two authors differed in their assignment of ν_2 and ν_7 , but their data are in good agreement except that Mathieu *et al.*³ reported a band at 160 cm⁻¹ which was not found by either Sacconi *et al.*² or by ourselves. We have observed the spectrum of K_2PtCl_4 to 40 cm⁻¹ and support Sacconi's results and assignment for the following reasons.

(1) The site symmetry of $[PtCl_4]^{2-}$ in the potassium salt is the same as that of the free ion. It is thus difficult to account for the triplet nature attributed to ν_7 by Mathieu *et al.* (2) The band near 110 cm⁻¹ assigned by Mathieu *et al.* to ν_2 is absent in the spectrum of Magnus's green salt, and can be assigned to a translational lattice mode of the potassium ions, three of which should be infra-red-active. We find additional lattice modes at 87.5 and 59 cm⁻¹, which may also be associated with the potassium ions.

We have made the first observations of ν_2 and ν_7 for K_2PdX_4 ($X = Cl$ and Br), of ν_6 for $KAuI_4$, and of the

complete far-infra-red spectra of $[M(NH_3)_4] [M'Cl_4]$ [$M, M' = Pd, Pt$]. Our assignments for the complex ions in these compounds are supported by the band width considerations: those bands assigned to a_{2u} modes are sharp and narrow, while those assigned to e_u modes are at least twice as broad. A similar band width effect is seen in $\nu(CO)$ bands for complexes of the type $M(CO)_2$ (π -arene).

Table 1. INFRA-RED-ACTIVE FREQUENCIES (CM⁻¹) OF SOME SQUARE-PLANAR IONS

	$\nu_2(a_{2u})$	$\nu_6(e_u)$	$\nu_7(e_u)$	Other bands
K_2PtCl_4	174.5	326	194	108.5, 87.5, 59
K_2PdCl_4	168	332	190.5	111, 90
K_2PdBr_4	106	254	136	80.5
$[Pt(NH_3)_4]^{2+}$	141.5	—	234	266, 82.5, 74
$[PtCl_4]^{2-}$	175	310	198	—
$[Pd(NH_3)_4]^{2+}$	144	—	226	263, 93, 80.5
$[PtCl_4]^{2-}$	174	321	187.5	—
$[Pt(NH_3)_4]^{2+}$	136.5	—	245	364, 288, 93, 83
$[PdCl_4]^{2-}$	163.5	332.5	224	—
$KAuI_4$	—	190.5	—	—

All the ions in the complexes $[M(NH_3)_4] [M'Cl_4]$ have site symmetry C_4 . There should not therefore be any splitting of existing degeneracies, but the Raman-active ν_1 in the free ions should become infra-red-active. We have not observed it, but we do find a weak-medium band at 266 cm⁻¹ ($M = M' = Pt$), 263 cm⁻¹ ($M = Pd, M' = Pt$) or 288 cm⁻¹ ($M = Pt, M' = Pd$). This is very low for ν_1 for any of the complex ions and we tentatively assign it to a combination of ν_7 of the ammine complex ions with a lattice mode. There is no evidence that the metal-metal interaction in Magnus's green salt has any significant effect on the infra-red spectra of the complex ions, as compared with K_2PtCl_4 and $[Pt(NH_3)_4]Cl_2$. In particular, the a_{2u} out-of-plane deformation bands of $[PtCl_4]^{2-}$ are constant in both frequency and intensity.

Methane-rich Perchloric Acid Flames

THE study of flames supported by the vapour of 72 per cent perchloric acid^{1,2} has been continued by an investigation into methane-rich premixed flames of perchloric acid. Perchloric acid flames have already been shown to have no effective lower flammability limit since a decomposition flame of the acid vapour alone can be stabilized². It has now been found that mixtures containing up to at least 84 per cent methane in perchloric acid are flammable; this corresponds to 20 times as much methane as in a stoichiometric mixture, whereas methane-oxygen mixtures are only flammable up to 61 per cent methane³, corresponding to 3.1 times as much methane as in a stoichiometric mixture.

The methane-perchloric acid flames were stabilized on cylindrical 'Pyrex' burners of internal diameter of 1.13–25.4 mm surrounded by a 65 mm jacket tube so that the flames were burning in an atmosphere of argon. The apparatus was preheated to 210° C by nichrome heating wire in order to maintain the perchloric acid in the vapour phase. All the flames were at atmospheric pressure.

Burning velocities, temperatures and burnt gas compositions were measured for flames containing 2–18 times as much methane as is required for a stoichiometric mixture. No carbon formation, as revealed by luminous yellow streaks or zones, was found with any of these flames. Burnt gas concentrations for methane, hydrogen, carbon monoxide, carbon dioxide and water in molecules per 100 molecules of initial methane are presented as a function of the mixture ratio, λ , in Fig. 1 (the diluent

water is not included). λ is defined as the fuel/oxidizer ratio in the mixture divided by the fuel/oxidizer ratio in a stoichiometric mixture. The other major product was hydrogen chloride and minor products were methyl chloride, chlorine and C_2 hydrocarbons.

The large amount of methane in the burnt gas is remarkable. It is possible to calculate an effective mixture ratio, ϕ , where ϕ is the fuel reacted/oxidizer ratio in the mixture divided by the fuel/oxidizer ratio in a stoichiometric mixture. The value of ϕ so calculated is 2 for any value of $\lambda > 2$. In other words, for flames containing more than twice the methane required for a stoichiometric mixture, the additional methane does not react and acts solely as a diluent. The flame temperatures measured with 0.002 in. Pt/13 per cent Rh-Pt thermocouples were compared with theoretical equilibrium temperatures calculated by (a) assuming that all the methane reacts, and by (b) assuming that only two moles react (that is, $\lambda = 2$) and that the rest of the methane acts solely as a diluent. The experimental temperatures confirm that methane-rich perchloric acid flames are in fact $\lambda = 2$ flames diluted with methane.

Carbon formation would not be likely in a $\lambda = 2$ flame (O/C ratio 2.0) and it is suggested that it does not occur in the richer flames because the flame temperature is insufficient. Addition of oxygen to methane-rich perchloric acid flames raises the flame temperature and carbon formation ensues. This observation supports the idea that carbon formation is not observed in the methane-acid flames because the flame temperature is too low.

Fig. 1. A, Methane; B, water; C, hydrogen; D, carbon monoxide; E, carbon dioxide

The finding that only two molecules of methane react per molecule of perchloric acid is interesting. It cannot be directly compared to the situation with methane-rich oxygen flames since there is a paucity of sampling data. The only comprehensive study is that made by Townend in 1927 into the explosion of methane-oxygen mixtures at pressures of 6–150 atmospheres⁴. If it is assumed that the carbon produced in his experiments came from the pyrolysis of unreacted methane during the cooling of the post-flame gases, it is possible to calculate an effective mixture ratio, ϕ , in the same way as has been done for perchloric acid flames. For mixtures with $\lambda = 4$ and 5 the value of ϕ is close to 2. Further discussion is unwarranted since it is not certain that carbon is formed in this way. It would be interesting to sample premixed methane-rich oxygen flames under increased pressure to determine whether methane-oxygen flames are also essentially $\lambda = 2$ flames.

A mechanism can be proposed for the basic steps in a methane-perchloric flame. These must be different from those in a methane-oxygen flame since: (a) methane-perchloric acid flames have burning velocities about three times faster than the corresponding methane-oxygen flame⁵; (b) addition of oxygen to methane-rich perchloric

acid flames results in the production of a second flame zone downstream of the acid zone¹. Consequently, it is suggested that initial attack of the methane is by reaction with chlorine-oxygen radical or a chlorine atom.

While ClO has been written as the chlorine-oxygen radical, since it has been suggested that it will be an efficient chain carrier⁶, other chlorine-oxygen species could equally well be written in its place.

BIOCHEMISTRY

Polymorphism of Lactate Dehydrogenase Isozymes in Pigeons

RECOGNITION of the molecular heterogeneity of enzyme in single organisms has offered a new dimension for studying the genetic control of enzyme synthesis. In the case of lactate dehydrogenase (LDH) five distinct type (isozymes) can be identified in most mammalian and avian tissues by the method of starch-gel electrophoresis¹⁻³. Each isozyme is a tetramer formed by the association of two monomers, A and B (ref. 4), so that the polypeptide composition of LDH-1 through LDH-5 respectively may be written as follows: A_4B_0 , A_3B_1 , A_2B_2 , A_1B_3 and A_0B_4 . Genetic investigations⁵⁻⁷ have shown that the synthesis of the A and B sub-units is under the control of two different structural genes, a and b. Hence the isozyme composition of each tissue depends on the relative activity of the genes at these loci.

The finding of unusual isozymes, 'band X' isozymes, in testes from sexually matured animals provided new information on the genetic control of LDH synthesis. The 'band X' isozymes are present only in mature testes, their appearance coincides with initiation of spermatogenesis, and they comprise the predominant isozymic forms of LDH in mature sperm⁸⁻¹⁰. These observations suggested that a third genetic locus was responsible for the synthesis of yet another distinct kind of LDH sub-unit, a C-polypeptide, in mature testis. Genetic evidence for the existence of this locus was the discovery of two allelic forms of the c gene in wild pigeons¹¹.

Therefore, at least three structural genes are involved in LDH synthesis. In the pigeon, assuming homozygosity for the a and b genes, three genotypes are possible: $\frac{abc}{abc}$, $\frac{abc'}{abc}$, and $\frac{abc'}{abc'}$. We now present evidence for allelism at the b locus, and thus have identified the genotypes that will be required for a future analysis of linkage relationships among the genes controlling LDH synthesis.

Racing homer pigeons, wild park pigeons, 'White Carneau', 'White King', and 'Silver King' pigeons were used in this investigation. Most of the racing homer and pure-bred pigeons were males, whereas the wild population comprised approximately equal numbers of males and females. Methods for preparation and electrophoresis of tissue homogenates and haemolysates, localization of

Table 1. DISTRIBUTION OF CLASSES I, II, AND III IN THREE DIFFERENT PIGEON POPULATIONS

	215	0	0	1.0	0

LDH isozymes in starch gel, dissociation and recombination of LDH polypeptide sub-units, and determination of total LDH activity were similar to those previously described¹⁰.

A survey of the isozyme composition of tissues from proximately 1,000 wild pigeons showed that in terms of its isozyme phenotype each bird could be placed into one of three major classes which arbitrarily have been designated I, II and III. Examples of each class of pattern for breast muscle are shown in Fig. 1. The class I pattern exhibits five areas of enzyme activity, LDH-5, -4, -3, -2 and -1, LDH-5, -4 and -3 being the darkest bands. The staining of LDH-1, -2 and -3 in the class II pattern of breast muscle markedly diminished. Only three areas of activity are present in the class III pattern. The darkest band has the same electrophoretic mobility as LDH-5, and the other two bands migrate more slowly than LDH-4 and LDH-3.

Heart zymograms of the same pigeons from which the breast muscle patterns were obtained are also presented in Fig. 1. The class I pattern exhibits most of its activity

in the LDH-1 area, and less in LDH-2. Two minor bands can be seen on the anodal side of LDH-1. Five isozymes are present in the class II pattern, and the distribution of activity among the isozymes appears to be in the proportions of 1:4:6:4:1. The pattern of the class III heart, except for intensity of isozyme staining, is identical to that of class III breast muscle. Several other tissues from each pigeon were examined. In general, the differences in patterns of tissues with predominantly B polypeptides, for example,izzard and kidney, paralleled the changes exhibited by heart. The characteristics of zymograms for tissues having mostly A polypeptides or equal amounts of each polypeptide were similar to those described for breast muscle.

In most mammalian and avian species adult heart muscle is rich in LDH-1 and LDH-2. Thus the presence of a major isozyme in the class III heart with an electrophoretic mobility identical to that of LDH-5 led to an investigation of some of its other physicochemical properties. When tissue homogenates from pigeons with class I patterns were heated at 70° C for 15 min, isozymes with two or more A polypeptides, that is, LDH-3, -4 and -5, were inactivated. Inactivation of the B polypeptides did not occur until homogenates were heated at 80° C for 15 min. The heat inactivation properties of the isozymes in homogenates of the class II and III heart were identical to those observed for the class I hearts. Inhibition investigations with para-amino-salicylic acid showed that concentrations of inhibitor which decreased LDH-5 activity in class I tissues did not alter the activity of the isozymes in homogenates of class I, II or III hearts.

These experimental results suggested that the major isozyme of the class III heart does not contain A polypeptides, but that it represents polymerization of a B variant, B', the electrophoretic mobility of which is identical to that of the A polypeptide. Likewise the class II heart pattern can be explained by assuming that equal amounts of the normal and variant B polypeptides are being synthesized. If the polypeptide compositions of the major isozymes in the class I and III heart patterns are designated B₁ and B', respectively, then the isozymic complement of class II heart would be as follows: B₁B', B₁B'₁, B₁B'₂, B₁B'₃, B₁B'₄. In order to determine if the B and B' polypeptides could combine to form functional enzyme units, a mixture of equal amounts of class I and III heart homogenates was treated with 0.5 M sodium chloride and 0.1 M phosphate and frozen for 24 h prior to electrophoresis¹². As shown in Fig. 1, dissociation and re-association of the polypeptides resulted in the appearance of two new isozymes, and the pattern resembled the zymogram of a class II heart.

The nature of the two minor bands on the anodal side of the major isozyme in class III tissues is unknown. Since the electrophoretic mobilities of the A and B' polypeptides are identical, then only one isozyme should be visible in the class III patterns. Two minor bands are also present on the anodal side of LDH-1 in the pattern of class I heart. Perhaps these minor components are related in some way to the synthesis of the B and B' polypeptides.

Evidence for the genetic control of the three classes of isozyme patterns was obtained by measuring their relative frequency in different populations of pigeons. The data listed in Table 1 show that the distribution of the three classes in the wild-type population agrees with that expected according to the Hardy-Weinberg law for a single pair of alleles. All the racing homer and pure-bred pigeons exhibited class I patterns.

A conclusive demonstration of the mode of inheritance of the different class patterns was accomplished by carrying out appropriate breeding experiments. Adult wild pigeons were classified by electrophoresing haemolysates of blood obtained from a wing vein, and only class II pigeons were selected for the breeding colony. Twenty-

Fig. 1. Lactate dehydrogenase isozymes in breast muscle and heart from classes I, II and III pigeons. The homogenates were electrophoresed simultaneously in the same starch gel, and the conditions for identifying LDH were identical. The patterns of a mixture of equal parts of class I and class III hearts before and after treatment with sodium chloride and phosphate and freezing are designated I + III and I + III (Recomb) respectively.

one offspring have been obtained from 11 matings, and the ratio of phenotypes (class I—*BB*: class II—*BB'*: class III—*B'B'*) is 4:11:6.

These findings unequivocally show that there is allelism at the *b* locus in wild pigeons. The biological significance of the three classes of patterns is unknown. The *B'* polypeptide has never been observed in tissues from racing homer or pure-bred pigeons, and only one of the 921 trapped wild pigeons was *B'B'*. This pigeon appeared healthy, and the total LDH activities of heart, thigh muscle, breast muscle and testis were normal. The successful production of *B'B'* pigeons in the breeding colony will facilitate more extensive studies on the selective advantage or disadvantage of the *B'* variant.

Metabolism of 5-Chloro-2-cyclohexyl-1-oxo-6-sulphamoyl Isoindoline, Clorexolone (M and B 8430)

CLOREXOLONE (M and B 8430) is a powerful oral diuretic¹ with pronounced antihypertensive properties even when administered in sub-diuretic doses². It has certain structural features in common with chlorothiazide and with chlorthalidone, but is unique in containing the cyclohexane-isoindoline structure.

Although the metabolism in animals of cyclohexane and its simple derivatives, for example, methylcyclohexanes, hexanols and hexanones, has been studied in detail by Williams *et al.*³⁻⁵, there is little information about more complex derivatives. We have, therefore, examined the fate of clorexolone in experimental animals, and to a lesser degree in man, with two objects in mind. We wished, first, to establish that the compound was not stored in the body, and, secondly, we required information about the principal metabolic pathways operating in man and in the most closely related—in this biochemical context—animal species.

Preliminary investigations showed that colorimetric and spectrophotometric methods of estimating clorexolone and its congeners were insufficiently sensitive to permit quantitative experiments to be carried out with doses that approached those used therapeutically. They were, however, adequate to permit the conclusion that, in

contradistinction to the thiazide diuretics, insignificant amounts of the parent compound were to be found unchanged in, for example, rat urine. We were also able to demonstrate, by thin-layer chromatography and infrared investigations, that the principal metabolite appeared to be monohydroxylated, possibly in the cyclohexane nucleus. It was clearly undesirable, however, to rely solely on techniques which depended on excessive dosages—absorption, excretion and metabolic patterns may be atypical in such circumstances—and most of our preliminary work was therefore carried out with clorexolone labelled with carbon-14 in the isoindoline methylene group (see formula).

It will be seen from the tabulated results of the three experiments, in rats, one beagle dog and one whippet that there is no significant accumulation of carbon after periods ranging from 48 to 72 h.

Recovery of ¹⁴C-labelled clorexolone after administration to two Wistar rats. Two Wistar rats, each weighing 220 g received an oral dose of ¹⁴C-labelled clorexolone (0 mg/kg) which was six times the dose necessary to produce a three-fold increase in sodium excretion. Each animal received 0.38 µc. of carbon-14

Table 1. PERCENTAGE RECOVERY OF ¹⁴C-LABELLED DRUG

Sample	Time (h)			
	0-24	24-48	48-72	0-72
Urine	40.1	5.5	0.2	45.8
Faeces	31.0	18.2	0.0	49.2
Total	71.1	23.7	0.2	95.0

Recovery of ¹⁴C-labelled clorexolone after administration to a beagle dog. A beagle weighing 12.5 kg received an oral dose of ¹⁴C-labelled clorexolone (0.34 mg/kg), which was approximately three times the dose necessary to produce a three-fold increase in sodium excretion. The total amount of radioactive compound administered was equivalent to 5.0 µc. of carbon-14.

Table 2. PERCENTAGE RECOVERY OF ¹⁴C-LABELLED DRUG

Sample	Time (h)			
	0-18	18-24	24-42	42-72
Urine	58.5	5.0	0.0	63.5
Faeces	—*	—*	27.5	27.7
Total	58.5	5.0	27.5	91.2

* The animal failed to produce any faeces in the first 24 h.

Recovery of ¹⁴C-labelled clorexolone after administration to a whippet. A whippet weighing 5.7 kg received an oral dose of ¹⁴C-labelled clorexolone (0.83 mg/kg), which was approximately eight times the dose necessary to produce a three-fold increase in sodium excretion. The total amount of radioactive compound administered was equivalent to 12.7 µc. of carbon-14.

Table 3. PERCENTAGE RECOVERY OF ¹⁴C-LABELLED DRUG

Sample	Time (h)			
	0-24	24-48	48-72	0-72
Urine	95.4	3.2	0.0	98.6
Faeces	—*	4.0	2.2	6.2
Expired CO ₂	0.0	0.0	0.0	0.0
Total	95.4	7.2	2.2	104.8

* The animal failed to produce any faeces in the first 24 h.

In the experiments involving the rats and the beagle the carbon-14 content of the samples was determined by means of an end-window Geiger counter, whereas in the experiment with the whippet a liquid scintillation technique was used.

We wished to confirm that the main metabolic change produced in the molecule involved the introduction of a single hydroxyl group and that the pattern of metabolism in the dog conformed closely to that operating in man. Preliminary investigations with the urine of volunteer had suggested that there was a great similarity between metabolic routes in man and dog.

Early experiments in which dogs received very large doses of non-radioactive clorexolone suggested the presence of three metabolites in the urine. After separation on silica-gel chromatoplates, using acetone as the developing solvent, these three compounds were visible as fluorescent spots when viewed in ultra-violet light or

7 μ g. Examination of the urine from the whippet which had received the radioactive compound, in a dose approximating to the therapeutic dose, confirmed that a whole of the administered carbon-14 was excreted in the form of these three metabolites, which will hereafter be referred to as compounds A_1 , A_2 and B . These experiments also established that there were no significant differences in the metabolic patterns of large or small doses.

Having established this fact, it was then possible to administer daily doses of unlabelled clorexolone at 1 g/kg a dog for 3 weeks so that enough urine could be collected to permit the isolation of these metabolites. Urine was collected daily and the three compounds were separated by extraction with ethyl acetate, thin-layer chromatography on silica and fractional crystallization.

Direct comparison, by chromatography and by infrared and mass spectrometry, of metabolite A_2 with an authentic specimen of 5-chloro-2-(3'-hydroxy-cyclohexyl)-1-oxo-6-sulphamoyl isindoline showed that the two compounds were identical. Complete identification of the major metabolite, B , has not yet been established. Infrared and nuclear magnetic resonance examinations suggest that it contains an equatorial hydroxyl group. The position of this group will be restricted to the 2' or 3' position, since A_2 is the equatorial isomer of the 3' position, and the 1' position has been eliminated by the nuclear magnetic resonance investigations. The chromatographic and infrared characteristics of metabolite A_1 suggest that it also is monohydroxylated in the cyclohexyl nucleus.

Three metabolites which had chromatographic and infrared characteristics identical with those obtained from dog urine have been similarly isolated from human urine. Thirty litres of urine were collected over a 2-day period from a patient who was receiving 50 mg of clorexolone orally each day. Metabolite B was obtained crystalline, but the other two compounds were more difficult to purify and their identification depended on physical characteristics in solution.

It is evident that neither clorexolone nor its metabolites are stored in body tissues and that, although the compound itself is not excreted unchanged, metabolism and elimination occur solely and completely by way of oxidative monohydroxylations of the cyclohexane nucleus.

We thank Miss H. N. Grant for preparing the ^{14}C -labelled material, and Drs. R. I. Reed and H. C. Hill for the mass spectrometric examinations.

Formation of Hydroxamates during Proteolysis by an Enzyme System from Yeast

DURING re-investigation of an enzyme system from yeast previously reported to form 'activated' peptides¹ extensive proteolysis was noted and enzyme-catalysed hydroxylaminolysis of protein was suspected as the source of hydroxamate formation². Acyl-enzyme complexes were visualized as intermediates rather than some form of 'activated' peptide originally suggested by Cooper *et al.*¹. The main evidence for the latter hypothesis had been the appearance, after paper electrophoresis of the products of the reaction in the absence of hydroxylamine,

of a band which gave a positive reaction to the hydroxylamine ferric chloride test. This test, however, may be misleading when conducted on paper³. The formation of hydroxamates from protein substrates by other proteolytic enzymes was also demonstrated² and is presumably analogous to the well known transamidation reactions recorded by many authors⁴⁻⁸. Such reactions have only been unequivocally demonstrated using simple substrates but have been invoked to explain the formation of plasteins^{9,10} and energy-independent incorporation of amino-acids into mitochondrial protein¹¹.

Some further characteristics of the yeast enzyme system are reported here. The crude yeast enzyme was prepared in essentially the manner described by Cooper *et al.*¹ and further purified by absorption on to a hydroxyapatite-cellulose column¹² in 0.01 M phosphate buffer, pH 6.8, and subsequent elution with 0.5 M buffer of the same pH. After extensive dialysis the protein was freeze dried. Enzyme reactions were carried out at 37° in 0.035 M Tris buffer, pH 7.5, in the presence of 'low salt' hydroxylamine¹³ (2.5–4.0 μ mole) in a final volume of 3.3 ml. Additions of amino-acids, etc., were made in the same final volume after the respective solutions had been adjusted to pH 7.5. Reactions were terminated by the addition of 21.3 per cent (w/v) trichloroacetic acid in 0.43 N hydrochloric acid (2 ml.). After centrifugation the extinction of the supernatant at 280 μ was observed. The supernatant (3.0 ml.) was also mixed with 6.6 per cent $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ in 0.1 N hydrochloric acid (0.5 ml.) and the extinction at 540 μ observed after 5 min. Owing to the extreme sensitivity of the colour yield to minor changes in pH (ref. 14), the pH of the final mixture was observed and, before interpolating the hydroxamate concentration, the colour yield was corrected to pH 1.0, using graph of colour yield expressed as percentage of that at pH 1.0 plotted against pH. Glycine hydroxamate was used as a standard. Each determination was also corrected using a blank of identical composition to which trichloroacetic acid was added prior to addition of enzyme.

The formation of hydroxamates closely paralleled proteolysis in autolytic experiments (Fig. 1) and when additional protein substrate was present. Both activities are heat labile and reversibly inhibited by *p*-chloromercuribenzoic acid, thus resembling the more stable of the two enzymes obtained from yeast by Lenney¹⁵. Contrary to the earlier report¹, no evidence was found for any energy-dependent hydroxamate formation except

Fig. 1. Hydroxamate formation during autolysis of crude yeast enzyme in the presence of 2.7 mmole NH_2OH . Incubation time: 18 h. Increase in E_{280} μ (○); increase in E_{540} μ of Fe^{3+} /hydroxamate complex (●).

Table 1. EFFECT OF ATP ON HYDROXAMATE FORMATION DURING AUTOLYSIS OF YEAST ENZYMES

	Hydroxamate formed in 75 min (μ mole)	
Crude enzyme (15 mg), NH_4OH (3.7 mmole)	1.55	1.75
" " plus ATP (50 μ mole), MgCl_2 (33 μ mole)	1.24	1.43
" " plus ATP, MgCl_2 and amino-acid mixture*	1.15	1.24
" " plus amino-acid mixture only	1.00	0.85

* 8.3 μ mole glutamic acid and tyrosine and 20.6 μ mole methionine, phenylalanine and tryptophan in tris buffer, pH 7.5.

in the presence of amino-acids (Table 1). The highest yield of hydroxamate was, however, invariably observed in the absence of any additions. It is of interest to note that, in comparable experiments (Table 1), this system can produce up to 60 per cent of the hydroxamate observed in an apparently ATP-dependent system which was obtained by Schuur's *et al.*¹⁸ by a somewhat different procedure, from baker's yeast. The Dutch authors recognized that their system was proteolytic in nature and, most significantly, that added peptides could not be activated¹⁷.

It appears to be particularly difficult to interpret results based on the formation of hydroxamic acids when using crude enzyme systems which may contain proteases. This is especially true if trying to demonstrate peptide activation. Proof of such activation apparently requires a defined substrate and unequivocal identification of the reaction products¹⁸.

We thank Dr. A. H. Cook for his advice.

Hydrolysis of Two 17 α -Oestradiol Glycosides by Rabbit Tissue Glycosidases

It has recently been shown^{1,2} that the rabbit excretes 17 α -oestradiol as the 3-glucuronoside-17 α -N-acetylglucosaminide. To the best of our knowledge this is the first N-acetylglucosaminide of a non-sugar to be found in animals, although β -N-acetylglucosaminidase is widely distributed in animal tissues³. It was the object of the work recorded here to determine whether the steroid N-acetylglucosaminide was effectively hydrolysed by the tissue enzyme in rabbits, and whether the enzyme distribution, when measured with this naturally occurring substrate, was the same as that found by previous investigators^{3,4} who used synthetic substrates. We also wished to compare the relative ability of different tissues to remove the glucuronic acid and the N-acetylglucosamine from the oestradiol molecule.

Four rabbits were injected subcutaneously with 50 μ g day of oestrone benzoate in sesame oil. On the second an intravenous injection of 50 μ c. of 17 β -oestradiol-6,7 (sp. act. 150 μ c./ μ g) was also given. Oestradiol glucuronoside-17 α -N-acetylglucosaminide was isolated from the urine as previously described². A sample of di-glycoside was incubated in 0.5 M acetate buffer pH 5.0 with β -glucuronidase ('Ketodase', Warner-Cott). Oestradiol-17 α -N-acetylglucosaminide was extracted from the buffer with ethyl acetate and purified by countercurrent distribution¹. After crystallization from aqueous methanol, the product had a specific activity of 156 μ c./mmole. Another sample of the glycoside was incubated in 0.5 M citrate buffer at pH 4.2 with almond emulsin in the presence of 10 mg/ml. saccharo-1,4-lactone. The buffer was extracted exhaustively with ethyl acetate and the extract distributed through 99 countercurrent transfers in ethyl acetate-butanol-water, 3:1:4. A single radioactive product with a *K* value of 5.2 was located. This material was dissolved in water and, on the addition of a few drops of chloroform, yielded a semi-crystalline product of specific activity 167 μ c./mmole. The infra-red spectrum of this compound confirmed its structure as an oestrogen glucuronoside, a treatment of the material with β -glucuronidase yielded 17 α -oestradiol.

Oestradiol-17 α -N-acetylglucosaminide has an extremely low partition coefficient between chloroform and water. That of the 3-glucuronoside is even lower. A convenient method of measuring the hydrolysis of these glycosides by tissue enzymes was therefore to extract the released steroid from the incubation medium and assay the radioactivity in the extract by liquid scintillation spectrometry. In our hands this method has given accurate and reproducible results, and chromatography of the extract has shown that the chloroform-soluble radioactive material liberated from both glycosides by tissue enzymes is unchanged 17 α -oestradiol.

Organs were dissected from rabbits immediately after killing. Aliquots of the tissue were homogenized in acetate buffer at pH 4.5 and in citrate buffer at pH 4.2. A 10 per cent w/v ratio of tissue to buffer was used in each case. Aliquots of homogenate were diluted to 10 ml. with the appropriate buffer, and the radioactive glycosides (about 100 μ g/g tissue) were added in 50 μ l of ethanol. β -Glucuronidase activity was assayed in acetate buffer using oestradiol-3-glucuronoside as substrate, and β -N-acetylglucosaminidase was assayed using oestradiol-17 α -N-acetylglucosaminide in citrate buffer⁵.

At buffer concentrations of 0.5 M, the β -glucuronidase of both liver and kidney displayed the two pH optima at 4.5 and 5.2, observed by previous workers⁶, with that at pH 4.5 predominant. If lower buffer concentrations were used, effects such as those obtained by Fishman were observed, in that several optima appeared, at rather variable, but usually quite acid, pH values. A similar problem was encountered when attempts were made to assay β -N-acetylglucosaminidase at low buffer concentrations, and a smooth pH curve with an optimum at 4.2-4.4 was only obtained at a citrate concentration of 0.5 M. Accordingly, the assays of both enzymes were carried out in 0.5 M buffers.

A comparison of the ability of rabbit tissues to hydrolyse the steroid glucuronoside and the N-acetylglucosaminide is shown in Table 1. The overall distribution of both enzymes is broadly similar to that reported by previous workers^{3,4} for the rat and mouse. Female rabbit liver shows a much higher glucuronidase activity toward the steroid substrate than any other tissue. The activity is nearly three times as high as that of male liver. In the rabbit, as in other species³, the epididymis has a very high level of β -N-acetylglucosaminidase, and this tissue has the lowest ratio of β -glucuronidase/ β -N-acetylglucosaminidase activity. The spleen of both sexes is remarkably active in hydrolysing both oestradiol glycosides—the female spleen

Table 1. HYDROLYSIS OF 17 α -OESTRADIOL GLYCOSIDES BY RABBIT TISSUES *in vitro*

Results are expressed as μ g of substrate hydrolysed per g of tissue at 37°. Incubations with liver tissue were for 4 h; with all other tissues the incubation time was 2 h.

Tissue (male; F, female)	Oestradiol-17 α -N-acetylglucosaminide	17 α -Oestradiol glucuronide	Ratio of β -glucuronidase to β -N-acetylglucosaminidase activity
Liver M	4.64	248.0	53.4
Liver F	6.52	696.0	105.7
Kidney M	38.64	51.87	1.34
Kidney F	48.93	69.72	1.42
Testis M	128.73	378.0	2.94
Testis F	191.10	372.96	1.95
Spleen M	2.94	7.14	2.43
Spleen F	2.73	9.24	3.38
Small intestine F	38.01	67.20	1.77
Large intestine F	30.45	90.72	2.98
Stomach	14.28	25.83	1.81
Uterus	16.59	54.81	3.30
Adipose	157.29	55.86	0.36
Salivary glands	13.86	45.57	3.29

showing the highest β -N-acetylglucosaminidase activity, on a wet weight basis, of any tissue tested.

The results indicate that oestradiol-17 α -N-acetylglucosaminide is cleaved, under *in vitro* conditions, by the β -N-acetylglucosaminidase present in rabbit tissues. Whether this reaction has any significance *in vivo* is being investigated.

Metabolites in Urine of Rats on Diets containing Aldrin or Dieldrin

Using a fly bioassay technique, Kunze and Laug¹ reported the presence of toxicant in liver, kidney, abdominal fat and urine of rats fed dieldrin or aldrin. They observed that the toxicant in kidney and urine occurred mainly in males, with traces only in females. This toxicant in a male kidney and urine differed from either dieldrin or aldrin because it could be readily destroyed by treatment with 2 per cent alcoholic KOH, a property not shared by the parent substances. Since these observations, a number of investigators²⁻⁶ have reported findings which indicate the presence of derivations of dieldrin and aldrin in tissues and urine. These are assumed to be metabolites and can be most readily distinguished from dieldrin and aldrin by their increased hydrophilic properties.

It is of interest to investigate these metabolic derivatives further by the use of electron-capture gas chromatography, a tool of great sensitivity in the detection and isolation of chlorinated insecticides.

Mature male and female Sprague-Dawley rats within a weight range of 250-350 g were fed diets containing dieldrin or aldrin for 120 days. Two levels of each insecticide were fed, namely 1 p.p.m. and 25 p.p.m. These corresponded respectively to average daily intakes of 0.015 mg and 0.375 mg per rat. A control group was maintained on a standard 'Purina' laboratory chow. Analyses showed this diet to contain no detectable aldrin or dieldrin within the limits of detection in a 100-g sample, but traces of DDT and related derivatives were found.

During the experiment, urine samples were collected at intervals and at termination a final sample together with liver, kidney and abdominal fat tissues. All specimens were extracted with ethyl ether, the extracts made to volume and suitable aliquots prepared for gas chromatography. Careful consideration was given to the possibility

that the 25 p.p.m. levels could be grossly toxic, or sufficiently embarrassing to the metabolic machinery to cause qualitative differences in response between high and low dosages.

The gas chromatographic analyses were carried out in a Barber-Colman 'Model 10' gas chromatograph, utilizing a 4-ft. U-shaped glass column. The column consisted of a 2.5 per cent coating of SF-96 on 'gas Chrom P', 100-120 mesh. The temperatures of the column and the electron-capture detector were 170° and 200° C, respectively. The detector cell applied voltage was set at 18 V for optimum detection of chlorinated hydrocarbons. The system was able to detect readily 15×10^{-6} μ g of aldrin, 20×10^{-6} μ g of isodrin and 40×10^{-6} μ g of dieldrin or endrin.

Illustrative tracings shown in Fig. 1 are representative of gas chromatographic determinations made on urines

Fig. 1. Representative gas chromatograms of the ether extracts of the urine from control and experimental rats. In all cases 2.5 μ l. solution injected represented 15 μ l. urine. Standard solution: 2.5 μ l. represents 2.25×10^{-4} μ g aldrin, 2.5×10^{-4} μ g isodrin, 2.25×10^{-4} μ g dieldrin, 3×10^{-4} μ g endrin, respectively.

from animals exposed to 25 p.p.m. levels of dieldrin or aldrin. It can be seen that relatively large quantities (approximately 5:1) of a metabolite designated No. 1, having a retention time longer than any of the drin standards, appears predominantly in male urine, and only small amounts in female urine. Smaller quantities of a second metabolite No. 2, with even longer retention time, can be observed in about equal quantities in male and female urine. The latter peaks are not to be confused with two of unknown origin that appear in the control urines of both sexes. It should be especially noted that aldrin and dieldrin produce the same metabolites No. 1 and No. 2. From the type of column used, the longer retention times for both metabolites indicate that they are more polar than the parent substances. Furthermore, on hydrolysis of the urine extracts with alcoholic KOH, both metabolites disappear. This is in contrast to dieldrin and aldrin, which are alkali-stable. The epoxidation of aldrin to dieldrin both *in vitro* and *in vivo* has been well established⁷ and can be readily confirmed in our tracings. What is of interest, however, is that the animals which were fed dieldrin also appear to excrete small amounts of aldrin in the urine. These results cannot be explained on the basis of aldrin contamination of dieldrin, within the range of detectability of aldrin stated earlier. Preliminary results, notably on kidney extracts, show that the profile of metabolites in this tissue is similar to that in urine, with preponderance of metabolite No. 1 in the male kidney and sensitivity to alkaline hydrolysis.

No gross toxic effects at the 25 p.p.m. levels of dieldrin and aldrin were observed. Further, the gas chromatographic tracings made on extracts from the urine of animals exposed to 1 p.p.m. did not differ from those exposed to the higher levels except quantitatively. Shorter oral exposure to aldrin or dieldrin of rats indicates a similar profile of metabolites. It is of interest to note, however, that in some preliminary intravenous trials only minimal amounts of metabolites were observed in urine.

PHYSIOLOGY

Electrical Activity in Human Uterine Muscle Strips

In spite of increasing interest in functional disorders of the human uterus and clinical investigation, the obstetrician has little control apart from stimulation of uterine contractions. Premature labour leading to prematurity is at the present time the greatest single preventable cause of neonatal morbidity and mortality¹⁻³. Much of the present-day investigation attempts empirically to use smooth muscle relaxants to prevent premature activity, without a basic understanding of the mechanism of normal uterine muscle control. It is not known, for example, how oxytocin exerts its stimulatory action on the gravid uterus.

We have succeeded in recording action potentials from human uterine muscle strips. The amplitude and speed of propagation of the potentials have been correlated with

the mechanical action in non-pregnant and pregnant human myometrial strips.

In the non-pregnant patients the muscle strips were carefully cut from the anterior fundal wall immediately following hysterectomy. Care was taken to keep the serosal surface intact. The strip was trimmed to approximately $45 \times 5 \times 2$ mm and immediately placed in a solution of Krebs solution, previously saturated with 95 per cent and 5 per cent CO_2 . Time elapsing from removal to muscle bath was approximately 5 min. In the pregnant cases the strips were taken from the incision site, which was made in the low transverse cervical region. Strips were occasionally removed from the anterior fundal region during sterilization procedures 2-4 days post-partum.

The muscle was then tied, serosal side up, to two clamps. One clamp was fixed while the other was connected to a Grass strain gauge. The muscle was then immersed in a bath of Krebs solution, maintained at 37°C with 95 per cent O_2 and 5 per cent CO_2 bubbling. The strain gauge was connected to one channel of a Beckman-Offner multichannel recorder. Two blunt glass-pore electrodes were then separately placed on the surface of the muscle (on the intact serosal surface) a measured distance, 5-10 mm apart. Each electrode was then connected to separate channels of the Beckman-Offner recorder. The level of the bath solution was adjusted to cover the muscle surface 1-5-10 mm to prevent drying and to maintain adequate nutrition and temperature control (Figs. 1 and 2).

In the pregnant strips, the initial action potentials recorded immediately before the onset of the contractile (Fig. 3). They have a characteristic configuration: an initial positive deflexion followed by a rapid negative deflexion, a rapid return to base-line with a slight overshoot to the positive side, then a slow decay to base-line.

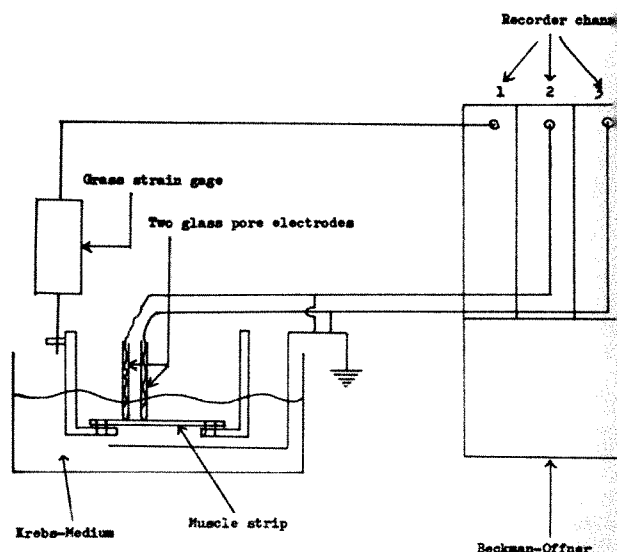

Fig. 1. Schematic illustration of technique used to record both mechanical activity and action potentials

Fig. 2. Smooth glass-pore electrode used for recording action potentials

Fig. 3. Electrical and mechanical activity recorded from a pregnant human uterine muscle strip. Compare the interval between the initial action potentials to that from the non-pregnant muscle. Paper speed 30 mm/sec or 6 squares/sec

Fig. 4. Electrical and mechanical activity recorded from a non-pregnant human uterine muscle strip. Note the onset of the tension prior to the recording of the action potentials, also the distance separating action potentials from the two recording electrodes. Paper speed 15 mm/sec or 3 squares/sec

subsequent potentials are of lesser amplitude and do not show the initial positive deflexion.

In the non-pregnant strips the initial potentials are recorded after the contraction has begun (Figs. 3 and 4). The initial action potentials from a representative non-pregnant muscle averaged 0.189 mV and were propagated at an average of 0.69 cm/sec. The comparable figures for the initial action potential from a typical pregnant muscle were 0.35 mV and 13.3 cm/sec. This wide difference between voltages and conduction velocities of action potentials has also been found to occur in non-pregnant and pregnant rabbit uterine strips⁴.

If we assume that only an action potential can initiate uterine contraction, then in the non-pregnant muscle the recording of appreciable tension change before the first recorded action potential must result from the slow propagation of electrical activity. Calculations based on the maximum time required for propagation of the action potential from either end of the muscle to the electrode indicated that the slow conduction velocity could have explained the measured delay in the appearance of the action potential following the onset of contraction. Further studies will be required to establish that slow propagation is indeed the explanation for the delayed onset of action potentials in non-pregnant uterine strips. If the electrodes are randomly placed on the muscle surface and action potentials originate at random spots, we would expect on occasion to record the action potentials before, or earlier in, the contraction. To date there has been no evidence to suggest a specialized pacemaker in the uterus, though pregnant strips always propagated action potentials from the fundal area distally in the instances when the spatial origins of the strip were known.

The action potentials, following the initial one which were recorded throughout the contraction in the pregnant strips, appeared to be isolated and non-propagated. The absence of the initial positive deflexion also suggested that they are not produced by a wave of depolarization from an adjacent area. It is tempting to assume that the difference in the electrical activity in pregnant and non-pregnant muscle is due to the great difference in hormone balance present, and work is in progress on this aspect

of the problem. This work was supported by the Canadian Medical Research Council (grant MA 1656).

Release of Plasminogen Activator by the Isolated Perfused Dog Kidney

Blood contains a proenzyme, plasminogen (profibrinolysin), which is converted to the proteolytic enzyme plasmin (fibrinolysin) by plasminogen activator. The level of plasminogen activator in the blood is increased in conditions of stress and after injection of epinephrine or nicotinic acid^{1,2}. The origin of blood plasminogen activator has not been established with certainty although it has been suggested that it may be derived from the plasminogen activator activity found in association with the endothelial lining of vessel walls³⁻⁵. In dogs, blood fibrinolytic activity can be increased by intravenous injection of a number of vasoactive drugs^{6,7}, but vasodilative drugs (for example, histamine) appear to be more effective than vasoconstrictive ones⁸.

We have studied the effect of histamine on the release of plasminogen activator by the isolated perfused dog kidney. A total of seven experiments were performed, using healthy mongrel dogs anaesthetized with 'Nembutal' (25 mg/kg). One kidney was removed to serve as control. The contralateral kidney of the dog was carefully freed from surrounding tissues, and the renal artery and the renal vein were ligated at their junction with the aorta and vena cava, respectively. A polyethylene catheter was inserted into the renal artery and another into the renal vein and the kidney perfused *in situ* with unoxygenated Locke's solution (pH 7.3) at 37° C until the effluent fluid had become completely clear and virtually free of red blood cells. Clearance of blood required from 180 to 480 ml. of Locke's solution. The effluent fluid during this initial perfusion period was collected in 100-ml. flasks. The kidney was then further perfused with Locke's solution and the perfusate collected as serial 5-ml. aliquots. At intervals histamine phosphate (Burroughs Wellcome and Co., Tuckahoe, N.Y.) was injected through the arterial catheter. The histamine was dissolved in Locke's solution at a final concentration of 1 mg base per ml. Each dose was 100 µg of histamine base per kg body-weight of the intact dog. The rate of perfusion was maintained at about 33 ml. per min throughout the whole experiment. Occasional red blood cells in samples of perfusate were removed by centrifugation at 4° C. The fibrinolytic activity of the perfusate was determined on unheated⁹ and heated¹⁰ bovine fibrin plates prepared as described previously¹¹. The protein content of the perfusate was measured by reading the optical density at 280 mµ and was expressed in terms of µg tyrosine per ml. Glutamic oxalacetic transaminase levels were measured according to the method recommended by the Sigma Chemical Co. (St. Louis, Missouri) and using their reagents.

For the histological study of plasminogen activator in kidney tissue, a modified Todd's technique¹² was used. Fibrin slides were prepared by clotting 0.6 ml. of a mixture of equal volumes of bovine fibrinogen solution (Bovine Fibrinogen, Behringwerke, Marburg/Lahn, Germany), 2 g per cent, and calcium chloride solution (0.05 M), with 0.1

ml. thrombin solution (Bovine Thrombin Topical, Parke, Davis and Co., Detroit, Michigan), 20 N.I.H. units per ml., on a 5 cm × 2 cm area of a standard microscopic glass slide. Veronal-hydrochloric acid buffer according to Owren¹³ was used to dissolve fibrinogen and thrombin. A block of tissue including a pyramid and its overlying cortex was excised in a transverse plane from the centre of the kidney. It was frozen at -20° C and sections 10 μ thick were cut with a freezing microtome. These sections were placed on the fibrin slides and incubated in a moist chamber at 37° C. After different intervals, slides were removed from the incubator and fixed in formaldehyde vapour and 10 per cent formol-saline solution. Afterwards, the slides were stained with Harris's haematoxylin and lithium carbonate and mounted in glycerine jelly.

The perfusate obtained before injection of histamine had low fibrinolytic activity and sometimes had no activity at all. In each experiment the injection of a first dose of histamine through the arterial catheter was followed immediately by the appearance of increased amounts of plasminogen activator in the perfusate. The perfusate had no measurable lytic activity on heated bovine fibrin plates, indicating that the active material was plasminogen activator. Injection of histamine was not followed by a significant change in the level of glutamic oxalacetic transaminase or in the protein content of the perfusate. Intra-arterial injection of a second dose of histamine after a short interval had no effect on the release of plasminogen activator into the perfusate. The results of a typical kidney perfusion experiment are given in Fig. 1.

The plasminogen activator content of frozen sections of the perfused, histamine-treated kidney and the contralateral control kidney was compared in each experiment; in 4 of the 7 experiments the histamine-treated kidney showed considerable decrease of the plasminogen activator activity normally found in association with the vasa recta¹⁴ of the subcortical zone. Fig. 2 demonstrates the decreased amount of plasminogen activator activity in a perfused kidney as compared with the normal, contralateral kidney of the same dog.

The presented data provide evidence that, in an isolated perfused organ, histamine stimulates the release of plasminogen activator into the perfusing fluid. The considerable depletion of plasminogen activator in the subcortical zone of four perfused kidneys suggests that the wall of the vasa recta is a source of releasable plasminogen activator. The fact that the level of glutamic oxalacetic transaminase, a common intracellular enzyme, does not increase suggests that plasminogen activator release is not accompanied by a significant degree of cellular necrosis.

Fig. 1. Fibrinolytic activity, glutamic oxalacetic transaminase level and protein content of perfusate of a kidney perfusion experiment. Histamine, 100 μg per kg body-weight of the intact dog, was injected through the arterial catheter at the times indicated by the arrows.

Control kidney

Perfused kidney

Fig. 2. Unstained sections of a control and perfused, histamine-treated kidney of a dog. Both sections were incubated at 37° C on unheated fibrin slides for 130 min. The dark areas indicate lysis of the fibrin layer. It can be seen that there is complete lysis over the subcortical zone in the control kidney whereas the section of the perfused kidney shows little lytic activity.

Tissular hypoxaemia may have played a part in the histamine-induced release of plasminogen activator since these experiments were performed on anoxaemic organ. It cannot be ruled out that histamine releases plasminogen activator by a direct effect on endothelial cells of small vessels or capillaries, although it has been impossible to demonstrate such an effect on walls of large veins. Injection of histamine into an isolated venous segment of the dog or incubation of an everted jugular vein of the dog in histamine solution does not decrease plasminogen activator content of the vessel wall^{8,15}.

A more likely explanation is that the release of plasminogen activator by histamine is attributable to the vasoactive effects of this drug. Assuming that the amount of plasminogen activator released is directly proportional to the area of perfused inner blood vessel surface, the opening up of a large number of small blood vessels by histamine in the perfused organ can be expected to increase plasminogen activator release.

We thank Dr. G. D. Penick for advice and Mrs. C. K. Taylor for assistance in this work, which was supported by grants from the National Institutes of Health (HE-06350) and from the American Cancer Society.

Thinning of the Human Cornea on Awakening

MUCH remains unknown about the mechanism whereby the cornea maintains its shape, thickness, and transparency. Maurice¹ points out that the observed negative water pressure inside the cornea and the positive

pressure in the aqueous humor and tears bathing the cornea should lead to continuous swelling and, therefore, corneal cloudiness. Some process, yet unknown, maintains the *in vivo* cornea at constant thickness and transparency. Mishima and Maurice² showed that whatever process operates to maintain constant corneal thickness, the process can be disturbed by closing the eyes for an hour or more. They showed that the rabbit cornea thinned by four per cent over a period of two hours after the eye was opened. The thinning was attributed to evaporation of solvent (water) from the tears to produce a hypertonic tear film which withdrew water from the cornea by an osmotic effect. Conversely, when the eye was closed and was bathed in isotonic tears, the cornea swelled. They considered the other two environmental factors which change when the eye is closed, namely temperature and oxygen tension, to be ineffective in changing thickness. The corneal temperature of the closed eye is about 4° C above that of the open eye. The oxygen tension of the epithelial surface of the closed eye must be about 50 mm mercury (the average between venous and arterial blood) whereas the open eye in air is exposed to 155 mm mercury oxygen tension.

The slow blinking rate of the rabbit (once every 10 min, compared with the human rate of 12 blinks per min) suggests that evaporation from the human eye may not be the same as from the rabbit eye. We have, therefore, measured the thinning of the *in vivo* human cornea after the eye is opened on awakening³.

The subject, a Caucasian female 20 years of age, was instructed to tape her left eye closed immediately on awakening in the morning, usually after 6-8 h of sleep. The tape was removed in the laboratory about 30 min later and corneal thickness measured as a function of time for several hours. Normal blinking was allowed at all times. Corneal thickness measurements were made by using a Vickers optical beam splitter fitted into one tube of a binocular microscope on a Thorpe-type slit-lamp⁴. The slit-lamp projects a vertical light beam about 1 mm wide and 1 cm long. In traversing the cornea it illuminates, by scattered light, the cross-section of the cornea that is observed in the microscope and beam splitter. By adjusting the beam splitter to give first a coincident image and then side-by-side images, the thickness can be obtained through a calibration which uses five corneal contact lenses of known thickness and refractive index. The calibration curve is shown in the insert of Fig. 1. The theory of such *in vivo* corneal thickness measurements has been reviewed by von Bahr⁵.

Because of the large spacial variation in the thickness of the human cornea, a critical feature of this experi-

ment was repeating the measurements at a constant corneal position. All parts of the slit-lamp assembly were rigidly fixed by clamps. The subject was held in a reproducible position by a dental-mould mouthpiece and head-bar which were fixed to a sturdy mounting on a weighted table. The standard fixation light on the slit-lamp was covered with a disk about 3 cm in diameter with a 1-mm hole in the centre. This provided a small fixation light to reduce eye movements. Only when the biomicroscope was properly aligned was a bright image produced by specular reflexion from the endothelium, and tear surface.

Measurements were made on four separate days. About ten settings of the beam splitter were made in each 5-min period for the first 80 min and then in 5-min periods separated by 15-min intervals for the remaining 80 min.

Fig. 1 shows a corneal thickness as a function of time. The cornea on awakening appears to be about 3.6 per cent thicker than normal. The normal-thickness base line was obtained by continuing the measurements, in some cases, to 6 h. The thickened cornea returns to normal in about 1 h.

The maximum corneal swelling of about 4 per cent is the same for rabbit and man. However, the rabbit cornea returns to normal thickness in 0.5 h (ref. 2) whereas the human cornea requires about 1 h. This can be explained by the lower blink rate of the rabbit. At this lower rate the tears concentrated by evaporation are replaced only infrequently, whereas in man there is frequent replacement of tears and, therefore, less-concentrated tears. Corneal thinning is probably caused by extraction of water by the osmotic pressure of hypertonic tears. A lower hypertonicity, accompanying the higher blinking rate in man, would give slower thinning.

We thank Miss Mary Linda Morrison for being the subject. The Vickers beam splitter was loaned to us by the Corneal Center, New York. This work was supported in part by U.S. Public Health Service research grants NB 04810 to R.B.M. and HE 06796 to I.F.

Use of Polyethylene Glycol in Investigations of Absorption of Fat

IN 1957 Borgström *et al.*¹ introduced the use of unabsorbable polyethylene glycol (PEG) for quantitative investigations of absorption of fat, protein and carbohydrate from the intestine. Stimulated by their communication, a number of authors²⁻⁴ used PEG to examine absorption. (After the administration of PEG and a food mixture of known composition in the withdrawn specimen of the intestinal contents the PEG concentration and investigated nutrients are estimated. From the two values the percentage ratio of the absorbed nutrient is calculated.)

Wiggins and Dawson⁵, however, directed attention to the fact that in the stomach a dissociation of PEG and the fat from the food mixture takes place; PEG remains mainly in the aqueous phase, which passes more rapidly into the intestine than the lipid phase. In a preliminary

Fig. 1. Time course of corneal thinning after opening eye on awakening from 6 h sleep. Insert shows calibration curve of beam splitter with contact lenses of various thicknesses. Corneal thickness is 0.92 times contact lens thickness at a given beam splitter reading for the optical system used here.

Table 1. INFLUENCE OF PEG ON THE LIPOLYTIC ACTIVITY OF HUMAN DUODENAL JUICE

Final conc. of PEG/ml.	Lipolytic activity as percentage of activity of control specimen Juice 1 (2.5 per cent l.)	Juice 2 (3.5 per cent l.)	Juice 3 (11 per cent l.)*
0.5	100	88.5	104
1.0	68	100	104
2.5	—	73.5	90
4.0	76.5	85.5	100
5.0	50.0	73.5	101

* Percentage of lipolysis in control specimens after incubation for 30 min. Composition of incubation medium: 0.2 ml. olive oil; 0.2 ml. phosphate buffer pH 6.5; 0.5 ml. PEG solution (1, 2, 5, 8, 10 mg/1 ml. duodenal juice).

experiment we investigated the stability of the food mixture (1 part olive oil, 4 parts dried milk, 1 part dextrose, 8 parts water) during incubation with human gastric juice, 1:1, at 37° C. It was revealed that the presence of PEG in a concentration of 5 mg/ml. distinctly promotes the breakdown of the food mixture.

The adverse effect of PEG on the stability of the emulsion system of the mixture brings up the question of how this substance participates in the breakdown of fats by pancreatic lipase. So far as we know, reports on this problem are lacking; we investigated therefore the effect of PEG on lipolysis in a model experiment *in vitro*.

As a source of lipase we used an aqueous 0.1 per cent extract of acetone powder of hog pancreas and fresh human duodenal juice. Olive oil served as substrate. The final concentration of PEG (molecular weight, 4,000) varied between 0.5 and 5 mg/ml. (In the experiment three different preparations of PEG were used. We thank Prof. B. Borgström and Prof. A. M. Dawson for kindly supplying specimens of PEG.) The exact composition of the incubation medium is given in the legend of Table 1 and Fig. 1. The degree of lipolysis was assessed from the difference of free fatty acids (NEFA) estimated in the incubation medium by Dole's method⁵ at the onset of and after the incubation. The results are expressed as the percentage activity of the control specimen which did not contain PEG.

In the experiment with pancreas extract it was found that in the presence of PEG the lipolytic activity was inhibited, depending on the concentration of PEG. As is apparent from Fig. 1, the inhibition is in general the greater, the smaller the amount of lipase in the incubation medium.

In the subsequent experiment we replaced the synthetic digestive mixture by human duodenal juice. It was revealed that also in this system PEG exerts an inhibitory effect (Table 1). Contrary to the first experiment, the effect of PEG rather varied; it attained a decrease up

Fig. 1. Influence of PEG on the breakdown of olive oil by an extract of hog pancreas. Composition of incubation medium: 0.1 ml. olive oil; 0.1 ml. 0.2 M CaCl₂; 0.2 ml. *tris* 0.2 M, pH 8.0; 0.2 ml. lipase extract; 0.25 ml. PEG solution 2, 4, 10, 16, 20 mg/1 ml.; 0.1 ml. H₂O. Incubation period 30 min. x axis, final concentration of PEG; y axis, percentage lipolytic activity of control specimen (without addition of PEG). ●, 0.1 per cent lipase extract; ○, 0.02 per cent lipase extract

to 50 per cent, however, not observed with low lipase activity. The inhibitory effect of PEG may be explained perhaps by its adverse action on the stability of the food mixture. This assumption requires, however, further confirmation. In any event, our finding supports the view⁶ that PEG is not very suitable for the accurate quantitative investigation of absorption of fat. A satisfactory reference substance should have the following properties: (a) it must not be absorbed; (b) it must not influence gastric emptying; (c) it must be soluble in the same medium as the substrate; (d) it must not affect the digestion and absorption of the investigated substance.

From experiments of Wiggins and Dawson as well as ours presented in this communication, it is obvious that PEG does not meet the latter two conditions, so far lipids are concerned.

Experiments *in vitro* revealed that PEG inhibits lipase from hog pancreas and human duodenal juice; it is therefore not very suitable for use as a reference substance for investigating absorption of fat, at least in conditions with low lipase activity.

PHARMACOLOGY

Some Effects of Drugs on the Isolated Superfused Carotid Body

THE isolated superfused carotid body preparation described by Eyzaguirre and Lewin¹, and used by them to investigate some properties of the carotid body, is a useful method for investigating chemoreceptor activity without need for concern about changes in the blood supply. This communication reports the results of an examination of the effects of a number of compounds on the activity of chemoreceptors in such a preparation. Some of these drugs would normally be expected to modify the blood flow through the carotid body and hence indirectly to affect the chemoreceptor activity. The changes in activity which they induce thus, here, represent the direct actions of drugs on the chemoreceptors. In addition, the effect of changes in the calcium ion concentration of the superfusate has been investigated because there is evidence²⁻⁴ that transmitter release at a number of sites may be related to calcium ion concentration.

The experiments were performed on the carotid body and sinus nerve removed from 18 cats lightly anaesthetized with sodium pentobarbitone. The superfusion technique was similar to that described by Eyzaguirre and Lewin¹ and the bathing fluid was Krebs's solution equilibrated with 95 per cent oxygen, 5 per cent carbon dioxide, maintaining the pH at 7.4. This was also confirmed by direct measurement. Five reservoirs were available so that different drug mixtures could be applied.

The sinus nerve was laid on a stainless steel back plate and dissected under liquid paraffin floating on the Krebs's solution in which the carotid body was suspended. Action potentials were recorded through a bipolar platinum wire electrode and the nerve impulses could be photographed from an oscilloscope and counted on a ratemeter with a chart recorder giving a permanent record.

The effects of a number of drugs were tested on the chemoreceptor activity when the rate of flow of the superfusate was increased so that the discharge fell to a minimum, and when a maximum hypoxic response was produced by raising the carotid body into the liquid paraffin.

former could be held constant over long periods and latter was repeatable.

acetylcholine (ACh) in a concentration of 10^{-4} – 10^{-5} M. always caused slight excitation, though adrenaline, noradrenaline (NA) and isopropylnoradrenaline (IP) added in concentrations of 10^{-5} g/ml. Lower concentrations were without effect. In two experiments, hexathonium bromide (C6) 10^{-5} g/ml. blocked the ACh excitation and was without effect on the hypoxic response, one the converse was the case and in the other this concentration was without effect. C6 alone did not change the resting rate.

The most consistent blocking effects were seen with thalidomide which, in concentrations of 10^{-5} g/ml., invariably depressed the resting discharge and depressed the hypoxic response. In addition, it blocked ACh and IP excitation. The results with dichloro-isopropylnoradrenaline (DCI) were more variable, but either it had no effect or depressed the resting rate and hypoxic response at 10^{-5} g/ml. Phenoxybenzamine in concentrations of 10^{-5} g/ml. increased the discharge rate at maximum flow, an effect which was slow in onset and long-lasting. In one test it blocked the excitation previously produced by NA. peridyl-methyl benzodioxane (933F) in low doses, 10^{-6} – 10^{-5} g/ml., similarly caused excitation. Neither drug had constant effects on the maximum hypoxic discharge rate, which was little changed.

Bretylium tosylate at a concentration of 10^{-5} g/ml. depressed the resting discharge and maximum hypoxic frequency and blocked ACh excitation. Its administration was also usually associated with depression of action potential amplitude.

The effect of reserpine could not be adequately tested, or it usually precipitated out in the superfusate.

In four experiments the effect of changing the calcium ion concentration was investigated. Superfusion with Krebs's solution containing no calcium chloride caused an increase in the spontaneous activity at maximum flow rate, while raising the calcium concentration by two or four times depressed this activity.

The experiments have also provided the opportunity for examining the statistical properties of the nerve impulse pattern. In three experiments single unit chemoreceptor afferent preparations were made and the distribution of intervals between action potentials was analysed in the manner described by Biscoe and Taylor⁵. This analysis showed that the mean interval and the standard deviation of twenty successive intervals were similar for mean intervals larger than approximately 300 msec, but that the S.D. became progressively smaller than the mean for intervals shorter than this. This result is similar to that previously obtained with the *in vivo* perfused carotid body⁶. An equality of mean and standard deviation is a property of a random interval distribution⁶.

It seems clear that ACh, NA, A and IP can all cause excitation of carotid body chemoreceptor afferents, presumably in this preparation by an effect other than on the vascular bed. High concentrations are required, and it is not necessary to suppose that ACh, for example, is acting here as a chemical transmitter, for its excitant effects on nerve endings are well known^{7,8}. The results with hexamethonium are equivocal, and on the basis of this evidence there can be no serious disagreement with Douglas⁹, or with the criticisms of the notion that ACh is a transmitter at this site^{10,11}. One of the more interesting results is the effect of nethalide, a β -adrenergic blocking drug, for its effect was consistently obtainable and unlike bretylium, for example, it did not depress the action potential height, an effect which may be related to the local anaesthetic action of bretylium^{12,13}. According to the theory expounded by Douglas and Rubin², and Douglas and Poisner³, and the evidence of Philippu and Schumann⁴, on release of catecholamine from the adrenal gland, the changes in activity produced by calcium should be the converse of those seen here if transmitter release were

calcium dependent. But the changes in activity with the calcium ion concentration are explicable in terms of direct effects on nerve endings¹⁴, and do not yield any information about transmitter release, if indeed a transmitter exists.

I thank Mr. J. O. Yates for his assistance.

Lethal Effects of Aggregation and Electric Shock in Mice treated with Cocaine

SENSORY stimuli provided by aggregation¹ or sub-maximal electric shock² become incompatible with life in mice treated with low doses of amphetamine. Effects of aggregation^{3,4} or electric shock⁵ on brain levels of norepinephrine are also modified by amphetamine. Amphetamine inhibits the uptake of norepinephrine by tissues *in vitro*^{6,7} and *in vivo*⁸. Termination of the biological actions of norepinephrine to a large extent depends on the tissue uptake or 'recapturing' of the free norepinephrine⁹. It is therefore postulated that toxicity of sensory stimuli in treated mice is partly due to the interference by amphetamine of the 'recapturing' of norepinephrine liberated from sympathetic nerves due to stimulation.

Cocaine, like amphetamine, also blocks the tissue uptake of norepinephrine *in vitro*^{10,11} and *in vivo*^{12,14}. The present report describes the lethal properties of sensory stimuli in the mice treated with cocaine.

Swiss albino random-bred male mice weighing 25–28 g were placed in shock apparatus or aggregation cages immediately after intramuscular injection of cocaine. All other drugs were injected intraperitoneally. The shock apparatus was similar to one described by Weiss *et al.*², while aggregation was according to Cohen and Lal¹. In isolation, only one mouse was placed in each cage, while 10 mice in a cage constituted aggregation. Shocks were provided for 4 h. There were no deaths with chlorpromazine or reserpine when given alone and the mice were aggregated. Reserpine produced some deaths among shocked mice.

Data given in Table 1 suggest that aggregation or shock became lethal to mice treated with sub-lethal doses of cocaine. As is seen from Table 2, the enhanced lethality of aggregation was completely prevented by pretreatment with adequate doses of chlorpromazine or reserpine.

Table 1. TOXICITY OF SENSORY STIMULI IN MICE TREATED WITH COCAINE

Cocaine, mg/kg	Experimental conditions	4-h mortality	
		Dead/injected	%
0*	Isolated	0/30	0
	Aggregated	0/30	0
	Shocked	0/20	0
50	Isolated	0/14	0
	Aggregated	1/20	5
	Shocked	5/24	20
100	Isolated	1/10	10
	Aggregated	13/20	65
	Shocked	15/24	63

* Mice were injected with 90 mg of sodium chloride per kg of body-weight.

Table 2. EFFECT OF CHLORPROMAZINE AND RESERPINE ON STIMULATED MICE TREATED WITH COCAINE*

Drug	Dose (mg/kg)	Experimental conditions	4-h mortality Dead/injected	%
Sodium chloride	90	Aggregated	13/20	65
Chlorpromazine	5	Aggregated	9/10	90
Chlorpromazine	20	Aggregated	0/10	0
Reserpine	5	Aggregated	1/10	10
Sodium chloride	90	Shocked	15/24	63
Chlorpromazine	5	Shocked	6/10	60
Chlorpromazine	20	Shocked	1/10	10
Reserpine	5	Shocked	4/10	40

* 100 mg of cocaine per kg of body-wt. was injected 1 h after chlorpromazine or 4 h after reserpine into all the mice.

Chlorpromazine also protected shocked mice. Effect of reserpine in shocked mice was inconclusive since in shocked mice reserpine exhibited some toxicity of its own.

Recently several investigations have demonstrated rapid and specific uptake of circulating norepinephrine by tissues^{13,15,16}, sympathetic nerve endings¹⁷, and isolated granules from nerve endings¹⁸. In isolated perfused heart, more norepinephrine is lost by tissue uptake than by enzymatic metabolism¹⁷. Denervation¹⁹, which depresses tissue uptake of norepinephrine, produces supersensitivity to injected norepinephrine.

On the basis of these observations it has been suggested that intensity or duration of biological action of circulating or locally released norepinephrine is limited to a large extent by 'recapturing mechanisms'. Interference with these mechanisms by drugs or other procedures may result in increased and prolonged pharmacological effects of exogenously or endogenously released norepinephrine. Present studies of effects of sensory stimuli in presence of cocaine or amphetamine provide *in vivo* evidence of an exaggerated sympathetic syndrome. Excessive sensory stimuli liberate norepinephrine through central and peripheral sympathetic discharge. Inactivation of liberated norepinephrine by 'recapturing mechanisms' is prevented by cocaine or amphetamine, resulting in prolonged and intense action of norepinephrine on tissue, causing tissue damage and death. Pretreatment with normal noradrenergic blocking agents may provide protection against the exaggerated sympathetic syndrome.

Interference by the Carcinogenic 4-Nitroquinoline N-Oxide of Tryptophan and Indole Uptake in *Escherichia coli*

THE potent water-soluble carcinogen 4-nitroquinoline N-oxide (NQO) is remarkably versatile and thus represents a good means of discerning pre-requisites for carcinogenesis. NQO condenses readily with sulphhydryl groups; is mutagenic to bacteria, tobacco mosaic virus,

and *Aspergillus niger*¹; inhibits incorporation of phosphorus-32 into nucleic acids of Ehrlich ascites carcinoma cells²; induces nucleolar 'caps' in Chang liver cells³; inhibits growth of the flagellates *Ochromonas dan* *Euglena gracilis*, of *Corynebacterium bovis*, and of photosynthetic purple bacterium *Rhodospseudomonas palustris*. These growth inhibitions are competitively annulled by L-tryptophan; D-tryptophan is also effective. The competitive annulment ratio is 0.2 mg/ml. tryptophan NQO 2 µg/ml.

This growth competition suggests that NQO uptake mediated by a tryptophan transport mechanism⁴. Investigate this possibility, two tryptophan-requiring mutant strains of *E. coli*, T3 and T24 (cultures obtained from Dr. C. Yanofsky), both utilizing tryptophan indole were investigated. NQO was tested for interference with the inducible tryptophan permease of both strains by a modified Burrows and DeMoss⁵ technique. 24 mg (dry weight) log-phase cells were collected on 'Millipore' cellulose filter (0.05 µ pore size) and washed 80 sec with isotonic C- and N-free medium and the filtrate discarded. C- and N-free medium + tryptophan (indole) at equimolar concentrations was then washed over the cells for 40 sec and this filtrate collected. Absorbance of the medium + tryptophan or indole was measured before and after exposure to NQO by means of a Beckman DU spectrophotometer set at 280 mµ.

Table 1. INTERFERENCE BY 4-NITROQUINOLINE N-OXIDE OF L-TRYPTOPHAN AND INDOLE UPTAKE IN *E. coli* (Readings as absorbance at 280 mµ)

Additions	Readings before exposure to cells	Control (after 40 sec washing)	Cells exposed to 4 × 10 ⁻⁴ M NQO for 5 min (reading taken after 40 sec wash with C- and N-free medium)
NQO 4 × 10 ⁻⁴ M	0.002	0.0019	0.003
L-Tryptophan 0.5 × 10 ⁻⁴ M	0.43	0.30	0.42
Indole 0.5 × 10 ⁻⁴ M	0.195	0.04	0.15

Introduction of NQO at 4 × 10⁻⁴ M (shown by viability investigations to be non-inhibitory in a culture of the density) into the growing culture completely inhibited uptake of L-tryptophan and inhibited indole uptake by 80 per cent within 5 min (Table 1). Both strains behave alike.

These results are construed as supporting our earlier idea that ability to deceive tryptophan transport system may underlie the carcinogenic specificity of polycyclic carcinogens.

HAEMATOLOGY

Plasma Co-factors in Adenosine Diphosphate-induced Aggregation of Human Platelets

THE aggregation of washed human platelets *in vitro* by adenosine diphosphate (ADP) requires calcium and is stimulated by the addition of platelet-free plasma¹. The identity of the plasma activity has been the subject of recent conflicting reports. Hellem and Owren² have suggested that the plasma factor is that entity missing in von Willebrand's disease; but others^{3,4} have found that ADP-induced platelet aggregation proceeds normally in plasma from patients with established von Willebrand's disease. McLean *et al.*⁵ and Cross⁴ have indicated that fibrinogen may be the plasma co-factor, and Caen⁶ has

ently suggested that both fibrinogen and the anti-von Willebrand factor participate in ADP-induced platelet aggregation.

The experiments described here were undertaken in an effort to clarify the nature of the stimulatory activity of plasma on ADP-induced aggregation of washed human platelets. Platelets were collected and processed with ionized equipment from normal subjects and from a patient with established von Willebrand's disease, using an acid-citrate anticoagulant of Aster and Jandl¹⁷. Platelet-rich plasma was prepared by centrifugation at 5g for 15 min at 23° C. Platelet pellets were obtained by further centrifugation at 2,500g for 5 min at 4° C. The platelets were resuspended with a Pasteur pipette in McIntire's platelet buffer⁸, modified in that the final glucose concentration was 2 g/l. and the final pH was 7.5. The platelets were washed twice in the same buffer and were finally resuspended in the same medium at a final concentration of 7×10^8 /ml. The suspended platelets could be kept in this medium at 4° C for as long as 4 h with no evidence of spontaneous aggregation and with no diminution of sensitivity to ADP. Platelet aggregation was measured by turbidimetric methods similar to those of Born and Cross¹ and O'Brien⁹. To 1 ml. of platelet suspension were added saline, the plasma or serum fraction to be examined, and calcium chloride. The pH of the mixture was then titrated to 8.3 by the addition of 0.1 N sodium hydroxide, and the reaction was initiated by the addition of ADP. The final volume of the reaction mixture was 2.5 ml. The final calcium chloride concentration was 7×10^{-3} M. Final concentration of ADP was 10^{-4} M. The optical density of the suspension was determined at 60 mμ in a spectrophotometer placed over a rotating magnet. The platelets were continuously stirred by a 'teflon'-coated bar placed in the cuvette. The optical density contributed by the platelets was determined by adjusting to zero the absorbance of an identical reaction mixture in which platelet buffer replaced the platelet suspension. The optical density of the platelets was determined immediately and at 60 sec following the addition of ADP. The decrease in absorbance was expressed as the percentage of initial optical density:

$$\frac{\Delta \text{ optical density in 60 sec}}{\text{initial optical density}} \times 100$$

The stimulation of ADP-induced platelet aggregation by saline, by citrated human plasma heated to 56° for 10 min (from which the precipitated fibrinogen had been removed by centrifugation), by thrombin-free human serum heated at 56° for 10 min, and by human fibrinogen fraction I-0 is shown in Table 1. In the presence of saline alone some aggregation of platelets occurred. There was little additional aggregation when heated plasma or heated serum was added individually. Whole plasma produced a marked increment of platelet aggregation. Fibrinogen alone stimulated platelet aggregation, but not to the same extent as whole plasma. In contrast, the addition of heated plasma and fibrinogen together, or of heated serum and fibrinogen together, reconstituted the entire activity of the whole plasma. Identical results were obtained using whole plasma, heated plasma or serum drawn from the patient with von Willebrand's disease (Table 1). Heated plasma dialysed extensively against 0.154 M saline was as effective as non-dialysed plasma when added to fibrinogen. The entire activity of the heated plasma could be recovered in the fraction precipitated by ammonium sulphate at 45 per cent saturation. In other experiments purified human fibrinogen (94 per cent clottable protein) was used instead of fraction I-0 (70 per cent clottable protein). No significant differences were noted when the more purified preparation was used.

The concentration dependence of the ADP-stimulated reaction on whole plasma, on heated plasma in the presence of non-limiting amounts of fibrinogen, and on

Table 1. INFLUENCE OF WHOLE PLASMA, HEATED PLASMA, HEATED SERUM, AND FIBRINOGEN ON ADP-INDUCED AGGREGATION OF WASHED HUMAN PLATELETS*

Addition (ml.)	Δ Absorbance (per cent)	
	Normal †	von Willebrand ‡
Whole plasma, 0.8	29.1	36.5
Fibrinogen (5.5 mg/ml.), 0.3	8.9	8.9
Heated plasma, 0.8	2.9	4.1
Heated serum, 0.8	7.8	5.5
Heated plasma, 0.8 + fibrinogen, 0.3	27.9	37.0
Heated serum, 0.8 + fibrinogen, 0.3	29.9	32.5

* Stimulation of ADP-induced aggregation above that seen in the presence of saline alone. The average Δ absorbance of 5 experiments with saline alone was 9.3 per cent.

† Average of 4 experiments.

‡ In these experiments washed normal platelets were used. No significant differences were observed when von Willebrand platelets were used with either normal or von Willebrand plasma or serum.

fibrinogen in the presence of non-limiting amounts of heated plasma is shown in Figs. 1 and 2. The percentage decrease in optical density due to saline alone has been subtracted from each point plotted. The shape of the whole-plasma curve is complex. A plateau of activity was repeatedly observed between 0.05 and 0.12 ml. of plasma, suggesting the interaction of more than one plasma component. No plateau was evident in the heated plasma plus fibrinogen curve which demonstrated consistently greater activity than that of the corresponding concentration of whole plasma until maximum activity was reached. Similarly, no plateau was observed in the fibrinogen curve, which reached maximal activity at a final fibrinogen concentration of 0.34 mg/ml. Similar curves were obtained with the von Willebrand's plasma.

It is apparent that the heat-stable protein is not consumed in coagulation, since heated serum was as effective as heated plasma. It is also evident that the heat-stable plasma factor required for ADP-induced platelet aggregation is not missing in the plasma of a patient with classical von Willebrand's disease. The mechanism whereby fibrinogen stimulates the ADP-induced aggregation is not immediately apparent. It is clear, however, that the participation of fibrinogen is not dependent on a thrombin catalysed conversion to fibrin, since the aggregation proceeds fully in the presence of heparin. In addition, electron micrographs of ADP-induced platelet aggregates show no evidence of fibrin formation. These findings are similar to those reported by Caen⁶.

Fig. 1. Influence of plasma concentration on ADP-induced platelet aggregation. Solid circles indicate effect of increments of whole plasma. Open triangles indicate effect of increments of heated plasma in the presence of non-limiting fibrinogen concentration.

Fig. 2. Influence of fibrinogen concentration on ADP-induced platelet aggregation, in the presence of non-limiting heated plasma concentration.

These experiments demonstrate that at least two plasma factors, fibrinogen and a heat-stable plasma protein, distinct from the anti-von Willebrand factor, participate in ADP-induced platelet aggregation in the presence of human plasma.

A Modification System for Fingerprinting Haemoglobin

THE technique of 'fingerprinting' developed by Ingram¹ has proved to be of great value in the molecular analysis of haemoglobins. In principle, it is a combined paper electrophoresis and chromatography of the peptides released by enzymatic digestion of haemoglobin. This enables the location of a probably occurring difference to a particular peptide. The method has proved its importance especially in the detection of amino-acid differences in normal and abnormal haemoglobins. This communication describes a modified system for fingerprinting haemoglobins.

In Ingram's procedure the first stage, paper electrophoresis, is performed in Miehl's volatile buffer²: pyridine-glacial acetic acid-water (20:0.4:20 by vol.) pH 6.4. Another volatile buffer, pyridine-glacial acetic acid-water (1:10:20 by vol.) pH 3.6, is preferred when only one-dimensional electrophoretic separation is desired. Ascending chromatography (stage 2) using the solvent *n*-butanol-glacial acetic acid-water (30:10:10 by vol.) was used by Ingram in his first investigation. Baglioni³ has obtained improved separations with a solvent made up of pyridine-isoamylalcohol-water (35:35:30 by vol.).

The solvent butanol-acetic acid-pyridine-water (50:72:15:60 by vol.), as proposed by Hill *et al.*⁴, has also been used with success. The disadvantage of a system with the strongly smelling pyridine is that it requires special conditions.

In our work on animal haemoglobins we have found that buffer made from ammonia-formic acid, and a solvent made from 2,6-lutidine-water, are very satisfactory for fingerprinting of haemoglobins. Equal amounts of 1 M ammonia and 0.5 N formic acid are mixed (final pH 6.5). If one-dimensional electrophoretic separation is desired, ammonia (0.5 M)-formic acid (1 N) buffer of pH 3.6 is preferred. The buffers can be used several times, but the pH should be checked between each running.

Whatman paper 3 MM, dimension 48 cm × 38 cm, corresponding to the size of the apparatus used in our work (AB Analysteknik, Vallentuna, Sweden), is dipped into buffer and excess liquid removed by blotting firmly between sheets of dry filter paper. The paper is then placed on a horizontal siliconized glass plate, which is cooled with water. After application of the sample the moist paper is covered with a sheet of polyethylene, and a weight is placed on the glass plate. Since the apparatus consists of two electrophoresis cells two papers could be run at the same time. A voltage of 30 V/cm is applied for 2.5 h. The papers were dried at 60° in a current of air for not less than 1 h.

Descending chromatography in 2,6-lutidine-water (122:60 by vol.) was carried out for about 20 h. Since the solvent is running rather fast (3.5 cm/h) the bottom edge of the paper is serrated with scissors as this assists even flow of the solvent off the end and helps to straighten any irregular solvent front. The paper is again dried in a current of air at 60°. The peptide spots were revealed by dipping the paper into 0.2 per cent ninhydrin in acetone, and allowing development to take place at room temperature or in a warm place not more than 40°. When a specifically staining test was needed, the ninhydrin colour was blached by dipping the paper in a solution of 1 N hydrochloric acid-acetone (1:4)⁵ followed by development with the reagents for sulphur⁶, tryptophan⁷ and histidine⁷. Alternatively, the sequence ninhydrin-sulphur and tyrosine reagent⁸ was used.

In Fig. 1 are shown the fingerprints of tryptic digest of cattle haemoglobin *F* and *B* obtained with this system. More than 20 peptides can be seen. The details of the result will be given elsewhere⁹.

Fig. 1. Photograph of fingerprinting of cattle haemoglobin *B* and *F* in ammonia-formate buffer, pH 6.5, and 2,6-lutidine-water solvent.

PATHOLOGY

Blood Group Secretion Factors in Bronchogenic Carcinoma

As a continuing study of our original report which dealt with investigations of salivary blood group secretion in metastatic cancer patients¹, we undertook an analysis of the frequencies of secretion (Se) and non-secretion (sese) related to particular cancer sites. This approach has been used by Desai and Creger² in gastric cancer and by several investigators in benign disease conditions³⁻⁵. The original premise, as extensively used in blood types and disease analyses⁶, is that these genetic factors will remain stable and not fluctuate during a disease process.

As the numbers of cancer cases increased in the various categories of organ sites, our attention was drawn to the high secretion (Se) rate among the bronchogenic cancer patients. This selection of secretors did not appear in the other high-incidence tumours such as colon and breast cancers. We thoroughly reviewed, therefore, all the bronchogenic tumours in this series to eliminate any possible metastatic lesions and found 88 primary bronchogenic carcinomata falling into the three main histological divisions of squamous, undifferentiated and adenocarcinoma. Whether metastases had occurred or not did not concern us in this investigation since our observation was designed only to record ABO blood groups and the saliva secretor or non-secretor factors (Se or sese respectively).

Table 1 shows the secretor status of patients with the three histological types of bronchogenic tumours. According to the usual distribution of secretion of ABH in the saliva, 20-2 of these 88 patients should have been non-secretors, whereas only five appeared. One of the five non-secretors had a bronchogenic adenoma of questionable malignancy, but was included in order not to show any bias. The scarcity of non-secretion in each histological group shows that there is no selection for one type. A χ^2 test of significance reveals a high value when compared with our control series and indicates a probability inconsistent with a chance occurrence. The number of tumours in each histological group is comparable with a large national series⁷, and, therefore, supports the assumption that our case distribution is within reasonable bounds of experience gained from other studies.

Table 2 gives the ABO blood groups of lung cancer and control cases. Although an excess of group A individuals and fewer group O individuals were afflicted with bronchogenic carcinoma compared with controls, the χ^2 test does not reveal a significant deviation from the controls. Similar results have already been recorded by McConnell

Table 1. SECRETION FACTORS IN HISTOLOGICALLY PROVED PRIMARY BRONCHOGENIC CARCINOMA

et al.⁸, but their excess of A was only noted in cases of undifferentiated bronchogenic carcinoma.

This finding of excess secretion of blood group substances among patients with bronchogenic carcinoma seems to parallel to some extent the findings of Desai² in patients with stomach cancer. Both mucosal surfaces are potent secretors of blood group substances whereas, in contrast, we do not obtain a significant deviation in colon cancer where the mucosa is low in blood group substance. Two possible explanations immediately occur: (1) that water-soluble blood group substances attract or alter carcinogens, favouring neoplasia or, perhaps, (2) that Lewis substance, the material produced in greater quantity by non-secretors, might reject, because of its chemical configuration, a carcinogen making it less effective.

Another interesting possibility lies in the known content of sialic acids in blood group substances. This component of mucopolysaccharides adheres closely to cell surfaces and is known to affect the 'stickiness' of cells⁹. A combination of sialic-acid-containing mucoids, which are known to be elevated in lung cancer⁸, and a carcinogen could conceivably alter the mucosal cell surface by prolonged stimulation bringing about dysplastic and neoplastic changes. Whatever the actual mechanism involved, this finding offers a valuable lead in the future investigation of bronchogenic carcinoma.

Induction of Intestinal Tumours by *N*-Ethyl-*N*-nitrosourethane

INTESTINAL tumours, though very rare in laboratory rodents, have been induced by several types of carcinogenic agents, including polycyclic aromatic hydrocarbons, 4-dimethylaminostilbene, 2-acetyl-aminofluorene and radiation^{1,2}. However, so far, no such tumours have been induced by alkyl nitroso-compounds, which are able to induce tumours in many organs³. Attempts to induce tumours of the colon by repeated rectal application of diethylnitrosamine led to liver, but not to local, tumours⁴.

It is of interest, therefore, that when *N*-ethyl-*N*-nitrosourethane (ENU) in 50 per cent aqueous ethanol was given to rats, males and females, by intraperitoneal injections, 3 out of 6 rats which survived more than a year developed adenoma and adenocarcinoma of the mucosa of the ileum. The tumours were multiple and were found in two male and one female rat, killed 16.5, 20 and 18 months after the first and 6, 9.5 and 7.5 months, respectively, after the last of four doses of ENU, about 20 mg per rat, *in toto*. The tumours formed large cauliflower-type nodules, up to 1.5 cm diameter, obstructing the lumen, and caused enormous distension of this part of the intestine. Some of the nodules penetrated into the muscle layer of the intestinal wall. *N*-Methyl-*N*-nitrosourethane, the methyl-homologue, is only now being tested by the intraperitoneal route in rodents.

BIOLOGY

Influence of Hexadecane on Absorption of Carbon Dioxide by Plants

RESULTS of recent investigations concerning the influence of hydrocarbons and a petroleum oil on apparent photosynthesis in *Citrus sinensis*¹ and *Bauhinia blakeana*² have focused my attention on the significance of stomatal distribution in a plant's response to the application of hydrocarbons. For example, using infra-red carbon dioxide analysis with sequential multi-point sampling³, it has been shown that an application of a paraffinic hydrocarbon to either the upper or lower surface of the leaves of

Bauhinia blakeana results in a decrease of absorption carbon dioxide while a similar application to the leaf of *Citrus sinensis* results in a decrease of absorption carbon dioxide only when applied to the lower surface of the leaves. Since these results are corollary to the distribution of stomata in these species they suggest penetration only through stomata with consequential interference absorption. The present investigation was initiated in order to clarify further the role of stomatal distribution.

With the following exceptions, infra-red carbon dioxide analysis as previously described³ was used. Leaves *Heliconia humilis* were enclosed in water-cooled plastic chambers which permitted sequential sampling for 5-min periods from either the lower or upper surfaces. The leaves were sufficiently illuminated from above to obtain maximum apparent photosynthesis (carbon dioxide absorptivity from both surfaces). After a pattern of carbon dioxide absorption was established for both surfaces, applications of hexadecane were made using a settling tower lead from an aerosol container. The amounts of hexadecane were determined gravimetrically.

The result of an initial application of 79 $\mu\text{g}/\text{cm}^2$ on the upper surface is shown in Fig. 1a, while the result of initial application of 126 $\mu\text{g}/\text{cm}^2$ on the lower surface is shown in Fig. 1b. For clarification the dark period (respiration or carbon dioxide evolution) have been omitted. Corrections have been made for minor fluctuations carbon dioxide in air.

Initially, and as anticipated from the distribution of stomata in this species, approximately 20 times as much carbon dioxide is removed from the air stream passing over the lower surface as on the upper, a greater amount carbon dioxide is removed from the air stream passing over the lower surface⁴. With the application of hexadecane to either surface a depression of carbon dioxide absorption obtained. It should be noted that the application to the upper surface did not interfere with absorption from the lower surface; and, conversely, the application to the lower surface did not interfere with absorption from the upper surface. These results suggest the lack of complete hydrocarbon penetration at the levels used.

Recovery from the application appears to correlate with the dissipation of the hydrocarbon. Complete recovery from the application applied to the lower surface occurred in about 6 h, while complete recovery from the application to the upper surface was not apparent until after stomata opening the following morning. The variance between the time of complete evaporation of the hydrocarbon from the aluminium paper strips and complete recovery of carbon dioxide absorption can undoubtedly be attributed to the 'threshold levels' that result from sorption.

The results unequivocally demonstrate the significance of stomatal distribution in a plant's response to the

Fig. 1. Concentration, p.p.m. of carbon dioxide in air stream from 3 channels sampled sequentially. Each large dot represents one 5-min sampling period. Solid line represents evaporation of hexadecane from aluminium paper strips, $\mu\text{g}/\text{cm}^2$. a, Application to upper surface; b, application to lower surface. Dark periods not shown.

lication of hydrocarbons along with the nature and the amount of hydrocarbon applied. They also suggest, since these experiments no visual injury was apparent, a more ical definition of 'phytotoxicity'.

Social Companions and the Mother-Infant Relationship in Rhesus Monkeys

THE development of behaviour in a young primate is influenced by both the physical and social characteristics of its environment. Paramount among the latter is the mother¹, while later other infants are important as play companions². Previous investigations^{3,4} of group-living rhesus monkeys suggested that adult females, other than the infant's own mother, might also play an important part, both by themselves showing maternal, social, play, aggressive and other types of behaviour towards the infant and by influencing the nature of the mother-infant relationship. For example, one adolescent female which, with the male's support, frequently interacted with the two infants in the same group, made their mothers extremely restrictive. In consequence, the infants lived confined lives: while seven other group-living infants were recorded more than 2 ft. from their mothers in a mean of 37 per cent of our observation periods when 7-18 weeks old, these two practically never went this far from their mothers up to this age.

In the experiment recorded here we attempted to assess the extent to which such a factor operates in other group-living infants where the effect is not so obvious. Nine mother-infant pairs each living in groups of a male, three or four females, and their young, were compared with four mother-infant pairs living alone. In both cases the cages were 18 ft. x 10 ft. x 8 ft., communicating with an indoor room 6 ft. x 6 ft. x 8 ft. (ref. 5). Routine watches were made between 0900 h and 1300 h G.M.T. or U.S.T. for at least 6 h a fortnight until the infants were a year old. Data were recorded on check sheets by 0.5 min periods. The levels of significance are based on the Wilcoxon matched-pairs signed-ranks test, 1-tailed, unless otherwise stated.

Differences between the group-living and the isolated mother-infant pairs were of two main types. First, the isolate infants ranged more freely. They spent less time on the nipple, less time on their mothers but off the nipple, more time off their mothers (Fig. 1), went to a distance of 2 ft. from their mothers more often, and spent longer bouts off their mothers (all $P < 0.005$). An increase in distance between mother and infant from less than 2 ft. to more than 2 ft. was more often due to the mother moving away in the isolates than in the group-living pairs, and a decrease was less often due to the mother (both $P < 0.005$).

A second group of differences between isolate and group-living mother-infant pairs we ascribe to the absence of other social companions for the former. Thus, although the isolate infants went to a distance from their mothers more frequently than the group-living ones, the number of 0.5 min periods spent wholly more than 2 ft. from their mothers during the second half year was less. Similarly, the frequency with which the 2-ft. radius around the mother was crossed was greater for the isolates (both $P < 0.005$). The isolate infants thus returned to the proximity of their mothers more often. The proportion

Fig. 1

of attempts made by the infants to attach to the nipple which led to acceptance by the mother was lower for the isolates ($P < 0.04$, 2-tailed sign test). Furthermore, grooming of both infant by mother ($P < 0.005$) and mother by infant (not significant) was higher for the isolates.

The results thus indicate that the relationship between rhesus mother-infant pairs is influenced in at least two ways by other members of the group. The presence of other adult or adolescent females results in the young infant ranging less freely from its mother, the effect being mediated largely through the mother's behaviour. The presence of social companions results in the infant returning to its mother less often than it would in their absence, and in consequence being rejected by her less often.

ENTOMOLOGY

Bilateral Asymmetry: a Larval Polymorphism in some Argid Sawflies (Hymenoptera, Symphyta)

BILATERAL asymmetry is virtually unknown among insects, other than as a rare aberration. Pasteels¹ has briefly noted the occurrence of colour asymmetry in larvae of *Arga ustulata* (L.) in Belgium and the Tyrol. Intensive collecting in south-eastern England and north-western Scotland has shown British populations of *A. fuscipes* (Fallén) and *A. ustulata* feeding on birches (*Betula pendula* Roth. and *B. pubescens* Ehrh.) to consist of symmetrical and asymmetrical individuals. Both forms appear to be present in proportions too large to be attributable to recurrent mutation alone. Unfortunately, however, samples from particular localities have so far been too small to allow accurate frequency determinations. Nevertheless, assuming genetic control,

Figs. 1 and 2. Flat mount in 'Euparal' of cast cuticle of asymmetrical last instar larva of *A. fuscipes* showing detail of cuticle of first abdominal segment. Fig. 1, part of darker left side. Fig. 2, corresponding part of right side. Scale, 0.2 mm.

this phenomenon would appear to constitute a true polymorphism (Ford²).

The symmetrical larvae of both *A. fuscipes* and *A. ustulata* are pale green on both sides, while the asymmetrical forms have one side distinctly darker green than the other. In all British examples so far examined the left has been the darker side, contrasting with the condition described by Pasteels¹ from continental examples in which the right was always the darker. The asymmetry seems to be a property of the cuticle alone. In our material the deposition of melanin pigment was heavy in the cuticle of the left side but negligible on the right side (Figs. 1 and 2). On the dark side the pigment is concentrated into small, closely scattered, spots which appear to have coalesced to form larger areas at the bases of the major bristles (Fig. 1). This distribution of melanin has the effect of darkening the outward appearance of the underlying green pigment.

The larvae of *A. fuscipes* and *A. ustulata* are leaf edge-feeders, particularly on birches in Britain. Asymmetrical larvae have always been found in the field feeding with their darker left sides uppermost, and they will readopt this attitude after being disturbed. The food-plant leaves are considerably darker green above than below so that an asymmetrical larva correctly oriented is remarkably cryptic to the human eye when viewed from either side. In view of the selective advantage this type of asymmetry would appear to confer on edge-feeding larvae, it is remarkable that it is such a rare phenomenon. Even in *Arge* larvae presumably there must be some associated disadvantages which serve to maintain the polymorphism (Ford³).

The situation is further complicated by taxonomic difficulties. *A. fuscipes* and *A. ustulata* are very closely allied forms and their larvae cannot at present be separated with certainty. Preliminary breeding experiments suggest that the two 'species' may be only seasonal forms

of a single species. It is hoped to carry out larger-scale breeding work with material from different areas in order to solve the taxonomic problem. Genetic analysis means of large-scale rearings is also urgently needed. It should be noticed that the adult sawflies show no obvious asymmetry whatever their larval type.

Feeding Mechanism of Blood-sucking Arthropods

It now appears to be established¹⁻⁶ that blood-sucking arthropods feed, in the main, either from the lumen of a blood vessel or from a blood pool resulting from the laceration of blood vessels. Occasionally an insect which is a vessel feeder will take part of its nourishment from a blood pool; but, except for the mosquito, this appears to be of unusual occurrence. *In vivo* observations on no sensitized hosts have shown that a considerable number of argasid and ixodid ticks, at least one horsefly and the tsetse fly are pool feeders, while several fleas, three species of triatomine bugs and the bed-bug are vessel feeders. The present consensus of opinion is that the mosquito is largely a vessel feeder, although Gordon *et al.*¹ give reasons for believing that a proportion, at least, of the insect blood meal is derived from haemorrhages formed in the tissues.

While the list of arthropods on which investigations of this nature have been carried out may look imposing, there are, nevertheless, some significant gaps in our knowledge. Hitherto, for example, no information has been available for such medically important insects as the stable-fly, biting midges, simuliid flies and lice. It is in order to provide some of the answers that the investigations on the stable-fly (*Stomoxys calcitrans*), the valley black-gnat (*Leptoconops torrens*) and the hog-louse (*Haematopinus suis*), summarized in this communication, have been undertaken.

These investigations have shown that both the stable-fly and the valley black-gnat, on laboratory white mice, are true pool feeders. The stable-fly possesses a proboscis which is not unlike that of the tsetse-fly but the labellar teeth are much coarser. The proboscis is introduced into the tissues somewhat like a cylindrical drill, the stout labellar teeth producing a haematoma from which the fly feeds. On the other hand, the feeding mechanism of the valley black-gnat generally resembles that of the horse-fly, *Haematopota pluvialis*. The mandibles cut the tissues with a scissor-like movement while the maxillae move rapidly to and fro.

Observations on *Haematopinus suis* were carried out on the ear of a laboratory white mouse. Following the introduction of the proboscis into the skin, the haustellum is everted and the strikingly flexible stylet bundle probes the tissues until a suitable blood vessel is located. This work has shown unequivocally that the hog-louse is a true vessel feeder.

Arthropods which feed from small vessels have hitherto been known as 'capillary feeders'. The term 'capillary feeder' cannot, however, be regarded as strictly correct if the capillary is defined as a small vessel of approximately 7 μ in diameter⁷, since observations on feeding carried out over the past few years have shown that feeding is not generally from capillaries but usually from venules or small veins. The term 'vessel feeding' should replace 'capillary feeding' before usage fossilizes the expression.

Finally, attention needs to be directed to the difficulty experienced in translating succinctly into certain foreign languages the expressions 'pool feeder' and 'vessel feeder'; neither the term must be directly borrowed from English, which is not always satisfactory, or else requires cumbersome translating. The introduction of two terms derived from Greek roots is therefore proposed for more universal application, 'solenophage' (from the Greek $\sigma\omega\lambda\eta\nu$ = pipe and $\phi\alpha\gamma\omicron$ = eating) for vessel feeder, and 'telmophage' (from the Greek $\tau\acute{\epsilon}\lambda\mu\alpha$ = pool and $\phi\alpha\gamma\omicron$ = eating) for pool feeder.

MICROBIOLOGY

Metabolism of Nucleic Acids and Protein in Starving Bacteria

DURING an investigation of metabolic processes in starving bacteria we observed that a significant net synthesis of deoxyribonucleic acid (DNA) took place in *hem*¹; no increase in the amount of ribonucleic acid (RNA) and protein could be detected (unpublished results).

The procedure in the foregoing experiments was as follows. Log-phase cultures of *Escherichia coli* B grown in a minimal medium were collected by centrifugation at an optical density of about 0.200, washed and re-incubated in acetate buffer (pH 7) at 37° C with aeration. Samples for biochemical analysis were taken immediately after resuspension and at the time intervals indicated in Fig. 1.

Fig. 1. DNA, RNA and protein content in *Escherichia coli* B incubated in acetate buffer. The content of these macromolecules in the bacteria at 0 min is taken as 100 per cent

Chemical fractionation of the bacteria, as well as the determination of DNA, was carried out by Burton's method², RNA was determined according to Mejbaum³, and protein as described by Lowry *et al.*⁴.

As seen in Fig. 1, the amount of DNA increased during 90 min incubation by about 30 per cent, while no biosynthesis of RNA or protein could be observed. Thus we postulated that the nucleic acid's precursor pool must be in this case preferentially utilized for DNA synthesis which is, consequently, favoured in some way in the starving bacteria.

To verify this hypothesis on a similar but more specific system, we used a 'uracil-less' mutant of *E. coli* B, which is capable of synthesizing only about 5 per cent of RNA and protein if no uracil is added to the growth medium.

E. coli B U- was incubated in '3 × D'-medium⁵, to which 30 µg/ml. uracil was added. At an optical density of about 0.150, 0.02 µc./ml. of ¹⁴C-uracil (specific activity 6.5 µc./µmole) was added to the suspension, and the incubation was continued for a further 2 min. The suspension was then quickly chilled, centrifuged in the cold, and washed twice by cold physiological saline. The bacteria were resuspended at the same optical density in cold '3 × D'-medium containing no added uracil, and re-incubated at 37° C with aeration. Samples for analysis were taken immediately after resuspension and after 10, 20 and 30 min incubation.

Chemical fractionation was carried out by a somewhat modified form of the Schmidt-Tannhauser method⁶. The radioactivity of the acid-soluble, as well as of the DNA- and of the RNA-containing fractions, was counted in a gas flow counter on planchets, after having dried on them 200 µl. of the corresponding extracts.

The results are summarized in Table 1. It is evident that there is a steady increase in the radioactivity of the DNA-containing fraction, while the activity of the acid-soluble fraction decreases rapidly. There is also a temporary increase of the radioactivity of the RNA-containing fraction, which, however, is not very significant if the initial high activity of RNA is taken into account (see data under B in Table 1).

Table 1. PERCENTAGE OF RADIOACTIVITY FROM ¹⁴C-URACIL IN THE DNA, RNA AND ACID-SOLUBLE FRACTIONS

Fraction	0 min		10 min		20 min		30 min	
	A (%)	B	A (%)	B	A (%)	B	A (%)	B
DNA	5.1	100	9.5	186	12.4	243	13.9	272
RNA	80.7	100	88.0	109	84.3	104.5	84.0	104
Acid-soluble	14.2	100	2.5	17.6	3.3	23.2	2.1	14.8

A, Percentage of total radioactivity from all three fractions.

B, Relative change in radioactivity, compared with counts at 0 min

Table 2

Fraction	0 min		20 min	
	A*	B	A	B
DNA	8.4	100	16.8	200
RNA	72.0	100	80.7	113
Acid-soluble	19.6	100	2.5	13

*A and B as in Table 1.

Data comparable with those in Table 1, but obtained in another experiment of the same type, are shown in Table 2. In this experiment DNA was isolated after 20 min incubation of the bacterial culture, by Spirin's method⁷, and hydrolysed by 72 per cent perchloric acid, the bases being isolated and separated by paper chromatography⁸.

After elution of the ultra-violet-absorbing spots, measurable radioactivity was found only in the spots with the R_F corresponding to those of cytosine and thymine, the specific activities (c.p.m./µmole) being: for cytosine, 0.929; for thymine, 0.790.

The presence in thymine of radioactivity comparable with that of cytosine indicates that the radioactivity from ¹⁴C-uracil was indeed incorporated into DNA molecules. This incorporation proceeds in spite of the very limited endogenous pool of uracil and goes on even when incorporation into RNA stops altogether.

These data seem to support our assumption as to the preferential utilization of nucleic acid precursors for DNA

synthesis in bacteria, incubated under starvation conditions or in a deficient medium.

The starving bacteria, incubated in acetate buffer, contain also an amino-acid pool which is, however, not utilized for protein synthesis, as can be seen in Fig. 1. This observation may point to the possibility that the limited potentiality of utilization of energy for anabolic processes in the starving cells is also oriented in the first place toward DNA synthesis. If this assumption was also shown to be correct, it would indicate that in our systems the kinetics of biochemical reactions on the precursor's level are such that processes leading to DNA synthesis are favoured over those leading to the synthesis of other macromolecules.

VIROLOGY

Transmission of Guamá and Oriboca Viruses by Naturally Infected Mosquitoes

Most of the present knowledge about the ability of mosquitoes to serve as natural hosts for arthropod-borne viruses is based on two methods. The first consists of triturating the wild-caught mosquito and inoculating it into a laboratory animal; subsequent virus isolation proves natural infection of the mosquito but not ability to transmit. The second consists of infecting the mosquito on a viraemic laboratory host and demonstrating transmission by bite to another laboratory host. This method demonstrated the ability to transmit, but may not reflect what happens under natural conditions. The technique described here makes possible a demonstration of transmission by naturally infected arthropods.

Mosquitoes captured during the first half of 1964 in mouse- and chicken-baited traps in the Instituto Agronomico do Norte forest near Belém, Brazil, were identified while alive and liberated in screened holding cages (100 cm × 100 cm × 115 cm) in the forest. A separate cage was set up for each mosquito species examined. Families of 3-day-old Swiss mice with the mother mouse were placed in the cages to provide a blood meal. These mice were observed for subsequent illness on the chance that the wild-caught mosquitoes might have been naturally infected with arthropod-borne viruses and have transmitted them to the mice.

Between February 24 and June 30, 2,846 *Culex (Melanoconion) taenopus* females were released in their cage and 68 families of mice exposed, each for a 24-h period. Guamá virus was isolated from the blood of a mother mouse exposed on April 14.

Between January 30 and June 30, 2,860 *Culex (Melanoconion)* females, of a species morphologically similar to 'Culex No. 9' of Trinidad, were released in another cage and 109 families of mice exposed. Oriboca virus was isolated from a baby mouse exposed on May 9.

The transmission of Guamá and Oriboca viruses to Swiss mice by naturally infected *Culex (Melanoconion)* has thus been demonstrated. This same technique was used by Sérié *et al.*² to transmit yellow fever to laboratory

mice by the bite of naturally infected *Aedes simpsoni* in Ethiopia.

CYTOLOGY

Circulation in the Cell

THE rapidity with which cells respond to the presence of solutes or suspensions in their immediate vicinity has made the problem of the permeation of the cell matter of major interest, but the question of how substances are distributed once they have entered the cell has not commanded nearly so much attention. I shall propose that the rapid distribution of nutrients and reactants within the microcosm of the protoplast (that is inside the plasma membrane) is effected by an active circulatory apparatus, by which fluid is forced through pores by hydrostatic pressure, somewhat analogous to the apparatus by which a corresponding circulatory distribution is effected in the macrocosm of the animal body. The concept of the cell-circulation is based almost exclusively on work with the yeast cell; but there are many indications which suggest that the conclusions are generally applicable. Many cellular membranes, which were previously thought to be intact, have been shown by electron microscopy to possess systems of pores. Pores which have been first observed by electron microscopy have been afterwards observed by direct light microscopy.

The circulation-hypothesis explains the rapid distribution of cell-substances which is inconsistent with the diffusion hypothesis. The fact that cells continuously change in their ability to take up substances from the external milieu is indisputable. It seems unrealistic, however, to try to account for such changes by changes in the composition of the membrane because a minor change, which might accommodate one substance, would certainly alter the behaviour of the membrane to a variety of other substances. It seems essential that any hypothesis should require that the structural integrity of the membrane-systems should remain unaltered throughout the life of the cell. It is interesting in this connexion that Lehninger¹ has suggested: (a) that membranes are usually assembled *in situ*; (b) that protein synthesis is concerted with phospholipid synthesis in such a manner that the two syntheses are mutually dependent; (c) that membrane synthesis occurs by a process in which the lipid and protein components of the membrane serve as 'structural templates' for each other, to form a thermodynamically stabilized end-product; (d) that each membranous structure may produce new membrane from proteins and lipids present in the protoplasm by using the pre-existing membrane as a template.

Although genes might change by mutation to produce enzymes which might be able to synthesize new membrane-components which might be able to alter the selective permeability of the membrane, it seems unlikely that changes in permeability are primarily due to such a mechanism. It seems much more likely that genes controlling the entry of a substance into the cell do so by eliciting the production of an enzyme which converts the substance into a form which can pass through the cellular membrane. According to the receptor hypothesis², genes act only in response to the contact stimulus of an inducer. As a general corollary to this hypothesis, a large molecule which might not be able to pass through the intact barrier of the plasma membrane and which could not enter any 'normal' membrane in metabolically

ificant amounts (that is, in amounts detectable by changes in oxygen consumption and carbon dioxide production) might, nevertheless, be assumed to act as an indicator of enzyme activity at the molecular level. Minute amounts might be able to enter the cell-circulation by imperfections (due to pinocytotic pores or fissures) which would act as inductors of enzymes by making contact with the gene-receptor in amounts which might not be detectable by metabolic measurements.

In the circulation theory the permeability of each of the cell membranes is assumed to remain virtually unchanged throughout the metabolic processes, and no enzymes are assumed to be elicited which change the permeability of the membrane *per se*. This theory does not require that permeation be purely by diffusion nor does it include the possibility that permeation may be facilitated by specific energetic mechanisms. It is assumed that adaptive permeation in the yeast cell is usually effected by contact of large molecules with hydrolytic enzymes which have been induced by a few molecules of the inductor and that the enzymes are afterwards expelled to the cell wall, or the nucleoprotein layer. In the nucleoprotein layer³ the extra-protoplasmic enzymes, which were induced in the cell by adaptive processes, hydrolyse large molecules into smaller ones which move much more rapidly through the plasma membrane, possibly by facilitated transport. The nucleoprotein layer performs the same function for the yeast cell that the small intestine and the lymphatic system perform for a vertebrate organism.

After the plasma membrane has been passed and the substance has entered the cytoplasm, the cell circulation rapidly distributes the materials through the cytoplasm and inside the nuclear apparatus. The 'pump' controlling the cell circulation is located in the nuclear apparatus and establishes a flow from the cytoplasm into the interior of the nucleus that ensures a relatively rapid movement of materials from the external *milieu* to the surface of the chromosomes. The motive power for the pump is furnished by the 'pumping units' of Oestergren⁴, who proposed that the spindle is coated with units which carry on a 'pumping activity' by which the chromosomes are moved to the poles. Oestergren *et al.*⁴ have suggested that substances are transported on and within the spindle by a pumping activity which drives materials from the equator in the two opposite directions while the spindle substance remains stationary. The pumping activity carries both chromosomes and acentric bodies to opposite poles of the cell much as sailboats are driven by the wind. I have assumed⁵ that the pumping units ('spindle-micellae') are located in the spindle reservoir of the yeast cell (which corresponds to the resting telophase nucleus) enclosed within the nuclear membrane and oriented to pump cytoplasm through the nucleus over the surface of the diffuse chromosomes. In the yeast cell an exit port leads from the spindle reservoir into the nuclear vacuole and hydrostatic pressure inflates the vacuole to an almost perfect sphere. Two exit (extruder) ports in the vacuolar membrane permit the slow discharge of a ribbon of endoplasmic reticulum, the attached ribosomes (carrying messenger RNA) and other solid materials from the nuclear vacuole into the cytoplasm.⁶ But the solutes, especially the methylated nucleotides of the nucleolus, from which the transfer RNA is synthesized in the cytoplasm (on the surface of the mitochondria) pass rapidly through the membrane of the nuclear vacuole into the cytoplasm on the stream which enters the cytoplasm through this thin, readily permeable barrier. The membrane of the spindle reservoir is impermeable to nucleotides.

Fig. 1 shows the 'flow sheet' of the cell. (1) The cell wall is composed largely of polymers of hexoses or hexose derivatives. (2) The nucleoprotein layer is confined between the coarse network of the cell wall and the much less permeable plasma membrane and contains an abundance of a variety of enzymes which were produced inside

Fig. 1

the cell. (3) The plasma membrane is a typical, protein-phospholipid, biological membrane, impermeable to most sugars larger than hexoses. (4) The cytoplasm is a limpid fluid in which the cellular organelles are suspended. (5) A thick, relatively impermeable, protein-phospholipid membrane containing both entry (6) and exit (9) ports surrounds the spindle reservoir. The spindle reservoir contains the diffuse chromosomes (8) and the pumping units (7). The diffuse chromosomes are expelled into the nuclear vacuole (10) from the spindle reservoir where they become condensed chromosomes. Each particulate gene carried on the histone backbone (11) of the chromosome contains a proteinaceous receptor (12) and a double loop of structural DNA (13) on which messenger RNA (14) is synthesized. (18) The membrane surrounding the nuclear vacuole is very thin, easily permeable and quickly destroyed by most cytological fixatives. In life, it is maintained in a condition of turgor by the hydrostatic pressure of the nuclear pump. The endoplasmic reticulum and its attached ribosomes (15) are extruded into the cytoplasm through a port (16) in the vacuolar membrane. The nuclear vacuole contains the nucleolus (17) in which the nucleotides from which transfer RNA is later synthesized are collected and methylated. The cytoplasm contains mitochondria in three different states: transfer RNA is synthesized from nucleolar nucleotides on the surface of the mitochondrion (19). In this state, the mitochondrion absorbs ultra-violet and stains with uranyl acetate. (20) The mitochondrion is the site of fat synthesis and in this condition is highly refractile in the light microscope and electron transparent. (21) The cristate mitochondrion, closely associated with the endoplasmic reticulum, is the cytoplasmic source of ATP.

GENETICS

Schizophrenia as a Genetic Morphism

Huxley, Mayr, Osmond and Hoffer recently proposed¹ the hypothesis that schizophrenia was a genetic morphism. This was based on three main streams of evidence: (1) genetic; (2) clinical; (3) biochemical. Baldessarini and Snyder² criticized this hypothesis for being premature. But every hypothesis is premature, for once the basic data are well established hypotheses are not required.

As the biochemical-clinical member of our group, I will refer to certain errors in the Baldessarini critique.

The arguments on which the adrenochrome hypothesis was based depend not only on the presence of adrenochrome in tissues, but also on a very comprehensive number of facts recently reviewed by me³. The evidence is both indirect and direct, that is, based on the reports of many independent scientists that adrenochrome or adrenolutin was found by them in body fluids. These works have not been referred to by the two critics. Nor have they referred to work by Axelrod⁴ at the U.S. National Institute of Mental Health, who demonstrated the conversion of adrenaline into adrenochrome in salivary tissue.

They further state, "It is thus quite unlikely that adrenochrome or adrenolutin are unique biochemical factors in schizophrenia". We at no time claimed these chemicals were "unique to schizophrenia", but instead attempted to show that adrenochrome was present in normal people and was diverted in greater concentration to adrenolutin in schizophrenics.

They further suggested that the mauve factor first reported by Irvine⁵ and Hoffer and Mahon⁶ could be related to dietary factors. Had they read Irvine it would have been apparent this was one of the remotest possibilities, since dietary factors were investigated and excluded by Irvine. The Irvine and the Hoffer and Mahon factors are essentially alike although the Irvine factor may contain more components. Both methods were cross-validated against each other. The mauve factor test has been used routinely in three psychiatric centres in Saskatchewan for up to five years, and has consistently been related only to severity of the psychiatric condition. It will, therefore, follow from the critics' position that a main variable in production of these illnesses is dietary—a novel idea.

Identical *S* Alleles in Different Botanical Varieties of *Brassica oleracea*

SELF-COMPATIBILITY is rare in marrow-stem kale (*Brassica oleracea* var. *acephala*) and usually occurs only in plants which have *S* alleles low in the dominance series. In such plants, genes, independent of the *S* alleles, determine self-compatibility¹. In other botanical varieties of *B. oleracea* self-compatibility is common and this suggests that these varieties might have the *S* alleles of low dominance found in marrow-stem kale.

Five inbred plants of marrow-stem kale, each homozygous for a different *S* allele, four of which had been identified in self-compatible plants, were crossed as males

to Brussels sprouts (*B. oleracea* var. *gemmifera*), to a plants of dwarf curly kale (var. *acephala*), savoy cabb (var. *sabauda*), purple-sprouting broccoli (var. *italica*) to one wild cabbage plant. Each of the five *S* alleles identified in at least one of the botanical varieties. The allele *S*₂ was found in all the botanical varieties tested; it was active in 19 of the 48 plants examined (Table 1). Another allele, *S*₁₅, occurred in three of these varieties and the five *S* alleles accounted for more than one third the total number of *S* alleles present in these plants (out of 96).

Table 1. NUMBERS OF PLANTS IN WHICH THE *S* ALLELE WAS ACTIVE IN STIGMA

Botanical variety	No. of plants examined	<i>S</i> alleles			
		2	5	15	26
Brussels sprouts	30	10	6	2	0
Dwarf curled kale	9	2	0	2	2
Purple-sprouting broccoli	5	4	0	1	0
Savoy cabbage	3	2	0	0	0
Wild cabbage	1	1	0	0	0
Totals	48	19	6	5	2

In the stigmas of plants with unidentified *S* alleles, can always be recognized because it is active in combination with each of the fifteen different *S* alleles from marrow-stem kale, with which it has been tested. In kale, *S*₂ is recessive in the pollen with thirteen *S* alleles, incompletely recessive with one, and active with two others very low in the dominance series. Hence, the proportion of plants with *S*₂ active in the pollen to those with *S*₂ active in the stigma indicates the dominance of the other alleles in a sample. Of the ten plants of Brussels sprouts, which *S*₂ was active in the stigma, *S*₂ was also active in the pollen in six. This confirms that there is a higher proportion of *S* alleles low in the dominance series in Brussels sprouts than in marrow-stem kale. Of the four purple-sprouting broccoli plants which had *S*₂ active in the stigma, only one had this allele active in the pollen.

These results suggest that horticultural varieties of *Brassica oleracea* may differ from agricultural kales in having a smaller number of *S* alleles, more of which are low in the dominance series and which therefore allow a higher proportion of self-compatible plants. Such differences could be a direct consequence of the number of plants selected to produce basic stocks. A commercial variety of marrow-stem kale may be based on several hundred mass-selected plants, whereas a variety of Brussels sprouts may be derived from a few rigorously selected plants. Selection of a few plants would reduce the number of *S* alleles, and subsequent seed multiplication would favour the retention of partially self-compatible plants with *S* alleles low in the dominance series. Thus, Sampson² found in Calabrese green-sprouting broccoli (var. *italica*) that four plants from a population had only four different *S* alleles, and he observed that "this represents a remarkably high concentration of *S* alleles but may be due to sampling rather than to any intrinsic feature of broccoli population structure". The present results suggest that Sampson's sample may be representative of the broccoli population.

The high proportion of plants in the different botanical varieties, which have allele *S*₂, is surprising. It is unlikely that it has spread during the last century by cross-pollination between breeders' distinct basic stocks of cabbage, Brussels sprouts and curly kale. *S* alleles are remarkably stable (Lewis³ found no new alleles for self-incompatibility in 22 million gametes of *Oenothera*) so that independent mutation to allele *S*₂ in different botanical varieties of *B. oleracea* can be ruled out. In potatoes, also, *S* alleles appear to be very stable; Dodds⁴ found the same *S* alleles in diploid cultivated species and in polyploids of autotetraploid 'Andigena' potatoes. It is therefore probable that allele *S*₂ occurred in the ancestral *B. oleracea*, from which the present botanical varieties have evolved. In addition, because relatively small numbers of plants are selected to maintain basic stocks of these

etities, it is probable that S_2 must have some inherent selective advantage.

VETERINARY SCIENCE

Association of Adenoviruses with Bovine Respiratory Disease

A STRAIN (*WBR 1*) of bovine adenovirus (BA) was isolated in primary cultures of bovine kidney (BK) and found to be antigenically distinct from BA type 1 and type 2 (ref. 1). The *WBR 1* strain has therefore been proposed as the prototype strain of BA type 3.

To assess its pathogenicity for cattle, 8 colostrum-fed calves were inoculated intranasally on the day of birth with 10 ml. of BK culture fluid containing *WBR 1* strain and with a further 10 ml. intratracheally 24 h later. The inocula had a mean titre of $10^{4.0}$ TCID₅₀/ml. The calves were kept individually in isolation and then killed 4 days (3 calves), 7 days (3 calves) or 3 months (2 calves) after inoculation.

During the week following inoculation, the calves showed clinical evidence of disease manifested by pyrexia and a mucoid nasal or conjunctival discharge which lasted 4 days. One calf was dyspnoeic and two other calves died 3 and 6 days post-infection respectively. Five of the calves also developed a diarrhoea during the time of pyrexia. Virus was recovered either from the faeces or from nasal and conjunctival secretions for up to 11 days after inoculation; on one occasion, virus was recovered from the nose of a calf at 3 weeks. At necropsy, areas of consolidation, collapse and emphysema were evident in varying degree in the lungs of each calf. In calves killed at 4 days, the lung lesions were present mostly in the hilar region, whereas in those killed at 7 days, they extended to the periphery of most lobes. There was lymphadenitis of the lymph nodes draining the pneumonic lungs. In the calves killed 3 months after infection the gross pulmonary lesions were small and discrete.

Histological examinations indicated that the prime lesion was a proliferative bronchiolitis associated with necrosis and desquamation of epithelium. These changes resulted in occlusion of the bronchioles with consequent alveolar collapse. Typical adenovirus intranuclear inclusions, in varying stages of development, were present in the lungs, tonsils and tracheal mucosa, as well as in the retropharyngeal, mediastinal and bronchial lymph nodes. In the calves killed at 3 months both the gross and histological lesions were minimal and consisted of some degree of lymphoreticular hyperplasia accompanied by patchy areas of scar tissue.

Two control calves inoculated with uninfected BK culture fluid were killed for examination after 4 and 7 days respectively. Both calves remained normal and free of virus throughout and no macroscopic or histological evidence of infection was noted in either animal.

Two further calves were killed 7 days after inoculation with a comparable dose of *WBR 1* virus which had been pre-treated with trypsin to remove possible 'toxic' factors of the type associated with human adenovirus type 5 (ref. 2). There was a similar clinical response but, at necropsy, the gross lung lesions were minimal and comparable to those seen in the calves killed at 3 months after infection with untreated virus. Cells with inclusions were again present in the respiratory tract but were difficult to find. This finding suggests that the trypsin-sensitive factor associated with the virus assists in the production of the pneumonic lesions observed previously.

Virus was recovered *post mortem* from various tissues from all the calves inoculated with virus, including the lungs of the calves killed at 4 and 7 days or those which died, but not from the lungs of those killed at 3 months or from those inoculated with trypsin-treated virus (Table 1). Immunodiffusion tests on the sera of all the calves showed that adenovirus group-reactive precipitating antibody developed in 3-4 weeks after infection and could persist thereafter for at least 2 months.

These experiments indicate that the *WBR 1* strain of BA type 3 is pathogenic for calves, and the results will be reported in detail elsewhere³. Serological evidence has been adduced previously that adenoviruses are associated with bovine respiratory disease in the field⁴. In further investigations with paired serum samples from affected or in-contact cattle, significant increases in adenovirus group-precipitating antibody have been observed in approximately 30 per cent of 150 disease outbreaks over the past 2 years⁵. The majority of such outbreaks attributed to adenovirus infection have occurred during the winter months, with peak incidence during the earlier

months of the year. Available evidence suggests that significant increases in neutralizing antibodies to BA types 1, 2 and 3 occur in the sera of cattle involved in respiratory disease outbreaks in Britain⁶ and that it is also possible that further, undefined serotypes of bovine adenoviruses may be involved.

Hepatic Tumours in Ducks fed a Low Level of Toxic Groundnut Meal

THE toxicity of certain samples of groundnut meal has been shown to be due to fungal metabolites, collectively known as aflatoxin, produced by strains of *Aspergillus flavus*¹. The carcinogenic effect of such meals for rats, a species relatively resistant to the acute effect of aflatoxin, has been demonstrated²⁻⁴ and it has since been shown that crystalline aflatoxin is carcinogenic for these animals^{5,6}.

Young ducklings are the most susceptible animals to the acute effect of aflatoxin⁷. This communication describes the change found in ducks fed for a prolonged period on a ration containing a low level of toxic groundnut meal.

Thirty-seven 7-days-old Khaki Campbell ducklings (group A) were fed a commercial poultry ration free of aflatoxin to which was added 0.5 per cent toxic Brazilian groundnut meal which contained approximately 7 p.p.m. aflatoxin (assayed as aflatoxin B₁). Sixteen control ducklings (group B) of the same age and breed were fed the commercial ration without added groundnut meal. All birds received tap-water *ad lib*. They were brooded for the first three weeks in electrical tier brooders and thereafter housed in arks on pasture. Weights were recorded weekly for the first 14 weeks of the experiment. Deaths in both groups were recorded and tissues retained for histological examination. The survivors in both groups were killed fourteen months after commencement of the feeding trial.

Tissues were fixed in formal-saline, embedded in paraffin wax, sectioned at 7 μ and stained with haematoxylin and eosin. Liver sections were, in addition, stained with Masson's trichrome stain and frozen sections were prepared and stained with oil red O.

Plotting the mean weight of the birds in the two groups against time showed no significant differences in the slope of the two regression lines, but the differences between means for the groups were significant at week 3 (group A 11.6 oz., group B 15.2 oz. ($P < 0.05$)), week 4 (group A 16.0 oz., group B 22.3 oz. ($P < 0.01$)) and week 5 (group A 23.5 oz., group B 27.9 oz. ($P < 0.05$)) but not at any other time to week 11. From weeks 11 to 14 there was no longer a linear weight increase in either group; the controls remained at a higher mean level than the treated birds and this difference was highly significant ($P < 0.01$) on mean values alone.

During the first four weeks of the experimental period nineteen birds in group A died. On histological examination lesions consistent with poisoning due to aflatoxin were present in the liver of all of them although in the birds death was ascribed to other causes. In the following 7 months a further seven birds in group A died, or were killed, and in each of these hepatic lesions consistent with aflatoxicosis were present.

In group B four ducks died due to bacterial disease and two were killed because of severe trauma inflicted by their pen-mates. On histological examinations of livers from these birds there was no evidence of aflatoxicosis.

Fourteen months after commencement the survivors in both groups, consisting of eleven in group A and ten in group B, were killed. Macroscopic lesions were confined to the livers; those from birds in group A were atrophied, putty coloured and contained numerous yellowish focal lesions 1-2 mm diameter. In four of the six drakes there were, in addition, solid yellow-coloured nodules varying in size from 1 to 3 cm diameter. In four of the five ducks in addition to the small focal lesions, there were nodules in the livers between 0.5 cm and 2.0 cm in diameter. Group B, comprising six drakes and four ducks, one drake had a number of small irregularly-shaped necrotic lesions in the liver. Apart from this there were no other macroscopic lesions in the organs of the birds in this group.

The small focal lesions present in the livers of all birds in group A were lymphoid foci composed mainly of mature lymphocytes surrounding degenerating hyperplastic bile duct epithelium. There were no mitotic figures but, peripherally, there was infiltration, in some cases extensive, of lymphocytes between the hepatic cords. The larger nodules were liver tumours of two types: thickly encapsulated, vacuolated hepatomata composed of hypertrophic ballooned cells occasionally containing giant vesicular nuclei with very prominent nucleoli, and cholangiomata composed of dense masses of well-differentiated bile ducts (the cells of which showed very few mitotic figures) surrounded by a thin fibrous capsule. This variation in cell type is seen in hepatic tumours of rats fed aflatoxin and other carcinogens⁸. In the liver of one duck tumours of both types were present, in the drakes and two drakes there were hepatomata, and in two of the other drakes cholangiomata occurred.

After 14 months eight of eleven birds fed a ration containing 0.5 per cent toxic groundnut meal developed hepatic tumours whereas none occurred in ten birds fed the same ration without groundnut meal. The aflatoxin B₁ content of the tumour-inducing ration for ducks was approximately 0.03 p.p.m. compared with 0.4 p.p.m. required to produce hepatic tumours in rats within 18 months⁹. The single oral LD₅₀ dose of aflatoxin for male rats is 7.2 mg/kg⁸ compared with 0.4 mg/kg for male ducklings⁹. The relative susceptibility of ducks and rats to both the acute and hepato-carcinogenic effect of aflatoxin is therefore comparable.

I thank Dr. J. G. Campbell of the British Empire Cancer Campaign for Research, Edinburgh, for his advice and Miss C. N. Hebert of this Laboratory for statistical analysis.

Monday, October 18

ASTICS INSTITUTE, PLASTICS PROPERTIES DISCUSSION CIRCLE (at the Mandeville Hotel, Mandeville Place, London, W.1), at 3 p.m.—Mr. D. A. "Impact Testing and Brittle Failure".

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower St., London, W.C.1), at 5 p.m.—Prof. B. A. D. Stocker: "Salmonella genes—Structure and Genetics" (further lecture on October 25).*

BRITISH COAL UTILIZATION RESEARCH ASSOCIATION (in the Lecture Theatre, Institution of Civil Engineers, Great George Street, London, S.W.1), at 3.30 p.m.—Prof. B. D. Spalding: "Heat Transfer Aspects of Coal Utilization" (Fourteenth Coal Science Lecture).

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. J. H. Hamence: "The Public's Approach to Pesticide Residues".

INSTITUTION OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINES GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Whither Small V-form Diesel Engines?"

ROYAL INSTITUTE OF CHEMISTRY (at Enfield Technical College, Queensway, Enfield, at 7 p.m.—Mr. W. G. Busbridge: "Isotopes in Industry".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Dr. Charles Swithinbank: "A Year with the Russians in Antarctica".

Tuesday, October 19

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. D. McNally: "Are Stars Visible?"*

UNIVERSITY OF LONDON (at Imperial College of Science and Technology, London, S.W.7), at 1.30 p.m.—Mr. E. F. Schumacher: "Sources of Understanding. Is Observation Enough?"*

UNIVERSITY OF LONDON (at the Institute of Education, Malet Street, London, W.C.1), at 5.15 p.m.—Mr. John Maddox: "The Nuffield Foundation Science Teaching Project".*

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. C. D. Brown: "Design and Construction of the George VI Bridge Over the River Usk, at Newport, Monmouthshire".

RESEARCH DEFENCE SOCIETY (in the Physiology Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. D. Reid: "Life and Men in Medical Research" (Thirty-fourth Stephen Paget Memorial Lecture), followed by the Annual General Meeting.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—of R. King: "Energy". (Afternoon lecture for Sixth Form Boys and Girls in Schools in London and the Home Counties. To be repeated on October 26 and 27.)

UNIVERSITY OF LONDON (at Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. C. B. Alcock: "Problems with Solutions: Chemical View of High Temperature Materials" (Inaugural Lecture).*

SOCIETY OF CHEMICAL INDUSTRY (joint meeting of the Heavy Organic Chemicals Group and the Plastics and Polymer Group, at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. J. H. Briston: "The Use of Chemical Products in Packaging".

PLASTICS INSTITUTE, LONDON SECTION ENGINEERING SUB-GROUP (at the Wellcome Building, Euston Road, London, N.W.1), at 6.30 p.m.—Dr. C. Hendrick: "Quality Control in the Mass Production of Plastics Mouldings".

Wednesday, October 20

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, 11 Cane Road, London, W.12), at 2 p.m.—Dr. B. W. Meade: "Laboratory Aspects of Drug Overdose".*

INSTITUTION OF CHEMICAL ENGINEERS (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Dr. A. J. V. Underwood, J.B.E.: "Chemical Engineering—Reflections and Recollections".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Discussion on "Computer/Instrument Interfaces".

INSTITUTION OF MECHANICAL ENGINEERS, STEAM PLANT GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. R. Carstairs: "Six Years' Operation of Cyclone Boilers at Thornton Power Station".

SOCIETY OF ENVIRONMENTAL ENGINEERS (in the Mechanical Engineering Department, Imperial College, Exhibition Road, London, S.W.7) at 6 p.m.—Mr. D. J. Lewis and Mr. A. S. Evans: "Radio Frequency Interference Control".

OIL AND COLOUR CHEMISTS' ASSOCIATION (in the Small Physics Lecture Theatre, Imperial College of Science and Technology, London, S.W.7), at 7 p.m.—Mr. P. Fink-Jensen (Denmark): "Rheological Properties of Paint and Two New Instruments for Measuring Them" (European Co-operation Lecture).

UNIVERSITY OF LONDON (at the Institute of Neurology, National Hospital, Queen Square, London, W.C.1), at 7 p.m.—Prof. N. S. Sutherland: "Attention and Learning in Animals".*

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the South-East Essex Technical College and School of Art Chemical Society, at Longbridge Road, Dagenham, Essex), at 7.30 p.m.—Meeting on "Computer Applications in Chemistry".

Thursday, October 21

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. M. J. Brown: "Do We Need Cities?"*

UNIVERSITY OF LONDON (at Imperial College of Science and Technology, London, S.W.7), at 1.30 p.m.—Mr. Patric Dickinson: "Computer versus Creator".*

CHEMICAL SOCIETY (in the Large Chemistry Lecture Theatre, Imperial College, London, S.W.7), at 2 p.m.—Symposium on "Organic Chemical Approaches to Biosynthesis".

INSTITUTION OF CIVIL ENGINEERS, ENGINEERING MANAGEMENT GROUP (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Management Training for Engineers" introduced by Mr. D. L. Marples.

UNIVERSITY OF LONDON (in the Beveridge Hall, Senate House, London, W.C.1), at 5.30 p.m.—Sir George Dodder: "Scientific Progress and the Pattern of Medical Care". (First of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).*

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6 p.m.—Mr. E. Woodcock: "Cooling Coil Evaluation".

SOCIETY FOR ANALYTICAL CHEMISTRY, Biological Methods Group (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion Meeting on "Use and Abuse of Statistics in Biological Assays" opened by Mr. K. L. Smith.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 20 Portland Place, London, W.1), at 7.30 p.m.—Prof. G. Macdonald: "On the Scientific Basis of Tropical Hygiene" (Presidential Address).

UNIVERSITY OF LONDON (at Wye College, Wye, Ashford, Kent), at 8.15 p.m.—The Rt. Hon. Lord Northbourne: "Religion and Science".*

Thursday, October 21—Friday, October 22

POWDER METALLURGY JOINT GROUP OF THE IRON AND STEEL INSTITUTE AND THE INSTITUTE OF METALS, in association with the BRITISH METAL SINTERING ASSOCIATION (in the Hoare Memorial Hall, Church House, Great Smith Street, London, S.W.1), at 11 a.m. on Thursday and 10 a.m. on Friday—Annual Meeting.

Friday, October 22

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. B. D. Shaw: "Explosives".

Saturday, October 23

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. Poul Rovsing Olsen (Copenhagen): "The Greenland Eskimos and Their Music".*

Monday, October 25

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Wellcome Building, Euston Road, London, N.W.1), at 3 p.m.—Symposium on "The Changing Face of Reinforced Plastics".

PLASTICS INSTITUTE, PLASTICS PROPERTIES DISCUSSION CIRCLE (at the Mandeville Hotel, Mandeville Place, London, W.1), at 3 p.m.—Mr. E. B. Atkinson: "Flow Behaviour of Molten Polymers".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. E. G. Bowen: "The Welsh Colony in Patagonia".

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Council Room of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Dr. F. W. Gibbs: "Gunpowder Priestley and Dictionary Johnson".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Sir John Cockcroft, O.M., F.R.S.: "Competitive Nuclear Power".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.E.—I.E.R.E. COMPUTER GROUPS (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. W. J. Poppelbaum: "Opto-Electronics".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. J. T. Bull: "A.C. Traction Power Supplies" (Chairman's Address).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER or LECTURER (preferably with a special interest in analysis) in PURE MATHEMATICS—The Registrar, University College of South Wales and Monmouthshire, Cardiff (October 20).

ASSISTANT LECTURER or COLLEGE LECTURER (with an honours degree in agricultural science, chemistry or biochemistry with suitable postgraduate experience) in AGRICULTURAL CHEMISTRY—The Secretary and Bursar, University College, Dublin, Republic of Ireland (October 22).

ASSISTANT LECTURER (with a good honours degree or equivalent and preferably some research or industrial experience) in BOTANY; and an ASSISTANT LECTURER (with a good honours degree or equivalent and preferably some research or industrial experience) in ZOOLOGY—The Academic Registrar, Brunel College, Woodlands Avenue, London, W.3 (October 22).

COLLEGE LECTURER IN GENETICS in the AGRICULTURAL BIOLOGY DEPARTMENT, FACULTY OF GENERAL AGRICULTURE—The Secretary and Bursar, University College, Dublin, Republic of Ireland (October 22).

SENIOR LECTURER in MATHEMATICS—The Registrar, Loughborough Training College, Loughborough, Leicestershire (October 22).

COMPUTER OFFICER (with a suitable university degree and experience in computer programming and operation) at THE TIDAL INSTITUTE AND OBSERVATORY—The Registrar, The University, Liverpool, quoting Ref. CV/296/N (October 23).

KEEPER (with a good honours degree in botany and/or the Museums Association Diploma; an interest in economic botany, museum experience of fieldwork, and preferably a working knowledge of at least one modern foreign language) of BOTANY—The Director, City of Liverpool Museums, William Brown Street, Liverpool, 3 (October 23).

PHYSICS LABORATORY TECHNICIAN for a GROUP ISOTOPE LABORATORY—The House Governor (A), Charing Cross Hospital, London, W.C.2 (October 23).

CHIEF STOREKEEPER (with experience in the supply and maintenance of scientific or technical laboratories) in THE DEPARTMENT OF CHEMISTRY—Prof. Stanley Peat, Department of Chemistry, University College of North Wales, Bangor, Caernarvonshire, North Wales (October 25).

LECTURERS IN ENGINEERING MATHEMATICS—The Registrar, The University, Newcastle upon Tyne 2 (October 27).

CHAIR OF THERMODYNAMICS AND FLUID MECHANICS IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Secretary, The Queen's University, Belfast, Northern Ireland (October 30).

LECTURER (registered medical practitioner holding the D.P.M., with broad experience of different aspects of psychiatry) IN PSYCHIATRY—The Registrar, The University, Leeds, 2 (October 30).

SENIOR BIOCHEMIST to take charge of a routine CHEMICAL PATHOLOGY DEPARTMENT—The Secretary, Queen Mary's Hospital, Roehampton, London, S.W.15 (October 30).

LECTURER IN BIOCHEMISTRY—The Registrar, King's College (University of London), Strand, London, W.C.2 (October 31).

RESEARCH FELLOW (with an honours degree in a relevant subject and a minimum of two years postgraduate experience or training) IN RADAR AND SIGNAL PROCESSING IN THE DEPARTMENT OF ELECTRONIC AND ELECTRICAL ENGINEERING—The Assistant Registrar (Science and Engineering), The University of Birmingham, Birmingham, 15 (November 1).

LECTURER IN EDUCATION, and a LECTURER IN SOCIOLOGY/SOCIAL ANTHROPOLOGY AT THE UNIVERSITY COLLEGE OF RHODESIA AND NYASALAND—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 2).

MYCOLOGIST (with an honours university degree in science or equivalent, and preferably suitable research experience) IN THE SOIL BIOLOGY DEPARTMENT—The Director, An Foras Taluntais (The Agricultural Institute), 33 Merrion Road, Dublin 4, Republic of Ireland (November 4).

SENIOR DEMONSTRATOR (with a degree in psychology and preferably some research or teaching or professional experience) IN PSYCHOLOGY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, November 5).

SENIOR LECTURER or LECTURER (with an honours degree in zoology) IN ZOOLOGY at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 5).

CHAIR OF FLUID MECHANICS AND HYDRAULIC ENGINEERING at Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 12).

HEAD OF THE DEPARTMENT OF MATHEMATICS, South Australian Institute of Technology—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1, or The Registrar, South Australian Institute of Technology, North Terrace, Adelaide, South Australia (Australia, November 12).

CHAIR OF PHYSICS at Fourah Bay College, The University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 15).

LECTURER or SENIOR LECTURER in the School of Botany, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 15).

LECTURERS (with a good honours degree and a keen research interest in any branch of electronics and control engineering) IN THE ELECTRONICS AND CONTROL DIVISION, School of Engineering Science—The Registrar, University College of North Wales, Bangor, North Wales (November 30).

MASTER TO TEACH GEOGRAPHY AND MATHEMATICS—The Master, Dulwich College, London, S.E.21.

MASTERS TO TEACH (a) PHYSICS and (b) MATHEMATICS (sixth form work)—The Headmaster, Forest School, Snaresbrook, London, E.17.

POSTDOCTORAL FELLOW (preferably with some experience in X-ray crystallography) IN THE DEPARTMENT OF CHEMISTRY, to collaborate with Dr. B. Stevens in a study of the photochemistry and radiation chemistry of crystalline aromatic compounds—The Registrar, The University, Sheffield.

POSTDOCTORAL RESEARCH BIOCHEMIST to join a group engaged in studying the control of protein biosynthesis in animal cells—Prof. H. R. V. Arnstein, Department of Biochemistry, University of London, King's College, Strand, London, W.C.2.

PROFESSOR IN PHYSICAL CHEMISTRY—Prof. Harry E. Gunning, Head, Department of Chemistry, University of Alberta, Edmonton, Alberta, Canada.

RESEARCH ASSISTANT (Academic) IN THE DEPARTMENT OF PHYSICS to assist in an investigation into laser-induced surface damage under the direction of Prof. S. Tolansky, F.R.S.—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Design Method Symposium, University of Aston in Birmingham Designate (College of Advanced Technology), September 21, 22, and 23, 1965—Preprints. (Organized by the Design and Innovation Group.) Pp. 322. (London: Butterworths, 1965.) [149]

Jacksons' Millboard and Fibre Co., Ltd. Directors Report and Accounts, 1965. Pp. 12. (London: Jacksons' Millboard and Fibre Co., Ltd., 1965.) [149]

Royal Observatory Bulletins. No. 97: The Absolute Magnitudes of RR Lyrae Variable Stars. By Sir Richard Woolley, G. A. Harding, Annella I. Cassells and Jennifer Saunders. Pp. E1-E30. 4s. 6d. net. No. 98: Proper Motions and Radial Velocities of Hyades Stars. By F. A. Wayman, L. S. T. Symms and K. C. Blackwell. Pp. E31-E62. 4s. 6d. net. (London: H.M. Stationery Office, 1965.) [149]

The Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom. A Compendium of University Entrance Requirements for First Degree Courses in the United Kingdom (excluding part-time and external degree courses). Third edition. Pp. 219. (London: The Association of Commonwealth Universities, 1965.) 11s. 6d. [149]

University of Reading. National Institute for Research in Dairying—Report 1964. Pp. 164. (Shinfield, Berkshire: National Institute for Research in Dairying, 1965.) 7s. 6d. [149]

Anti-Locust Bulletin No. 42: The Abdomen of the Female Desert Locust (*Schistocerca gregaria* Forskal), with special reference to the Sense Organs. By Joan G. Thomas. Pp. 20+45 figures. (London: Anti-Locust Research Centre, 1965.) 8s. 6d. [149]

City of Liverpool College of Technology. Prospectus of Full-Time Courses, Session 1965-1966. Pp. 67. (Liverpool: City of Liverpool College of Technology, 1965.) [149]

Road Research Laboratory: Ministry of Transport. Road Research Technical Paper No. 74: Traffic Signals for High-Speed Roads. By Dr. F. V. Webster and P. B. Ellison. Pp. v+49+2 plates. (London: H.M. Stationery Office, 1965.) 4s. 6d. net. [149]

Other Countries

Conseil National de la Politique Scientifique, Bruxelles. Recherche Industrielle dans ses Relations avec la Croissance Économique. Pp. (Bruxelles: Conseil National de la Politique Scientifique, 1965.) [1]

World Health Organization. Public Health Papers, No. 27: Trends in Study of Morbidity and Mortality. By Dario Curiel and 13 other authors. Pp. 196. (Geneva: World Health Organization; London: H.M. Stationery Office, 1965.) 8 Sw. francs; 13s. 4d.; 2.75 dollars. [1]

Council on Research in Bibliography, Inc. Mental Health Book Review Index, Vol. 10, 1965. Compiled by the Editorial Committee and Contributing Librarians. Pp. xx+78. Annual subscription: 5 dollars. (New York: Council on Research in Bibliography, Inc., c/o Research Centre for Mental Health, New York University, 1965. Subscriptions etc. to Miss Lois Affler Paul Klapper Library, Queens College, Flushing, New York, 11367.) [1]

Canada: Department of Mines and Technical Surveys. Geological Survey of Canada. Index to Reports of Geological Survey of Canada from 1955. Compiled by J. F. Wright. Pp. xli+379. (Ottawa: Queen's Printer, 1965.) 10 dollars. [1]

National Museum of Canada. Bulletin No. 201 (Anthropological Series No. 68): Folk Ballads and Songs of the Lower Labrador Coast. By Edward Leach. Pp. viii+332. (Ottawa: Queen's Printer, 1965.) 5 dollars. [1]

Government of Madras. Report of the King Institute of Preventive Medicine, Gundy, for the period from 1 April 1960 to 31 March 1961. Dr. S. Govindarajan. Pp. 53+2. (Guindy, Madras: King Institute of Preventive Medicine, 1963.) [1]

Geological Survey of New South Wales. Mineral Resources No. 40: Geological Survey of the Coonabarabran-Gunnedah District with special reference to the Occurrence of Sub-Surface Water. By E. J. Kenny. Pp. 77+5. (Sydney: Department of Mines, 1965.) 12s. 6d. [1]

F. and M. Scientific Corporation, Avondale, Pennsylvania. Meth Bulletin No. 117: Gas Chromatography Methods for Biochemistry Medicine: Qualitative and Quantitative Lipid Analysis by Gas Chromatography. Pp. 14. (Avondale, Pennsylvania: F. and M. Scientific Corporation; London: F. and M. Scientific Europa, N.V., 1965.) [1]

National Academy of Sciences—National Research Council. Publications 1284: Laboratory Animals. 4: Graduate Education in Laboratory Animal Medicine, Proceedings of a Workshop, March 26-27, 1964, Washington, D.C. (A Report of the Institute of Laboratory Animal Resources.) Pp. vii+35. 1.25 dollars. Publication 1285: Laboratory Animals. 5: Workshop in Animal Technician Training, October 2, 1964, Washington, D.C. Report of the Institute of Laboratory Animal Resources. Pp. v+57. 1.25 dollars. (Washington, D.C.: National Academy of Sciences—National Research Council, 1965.) [1]

Canada: Department of Mines and Technical Surveys. Geological Survey of Canada. Paper 64-37: Manganese Occurrences in Canada (Preliminary Reports and Metallogenic Map). By A. G. Johnston and W. D. McCarty. Pp. iv+63. 75 cents. Paper 64-47: Lower Palaeozoic Sediments of Northwestern Baffin Island, District of Franklin. By H. P. Trettin. Pp. vi+75 cents. Paper 64-52: Flat River, Glacier Lake, and Wrigley Lake, District of Mackenzie and Yukon Territory. By H. Gabrielse, J. A. Roddick and S. Blusson. Pp. 30+3 maps. 75 cents. Paper 65-11: Mineral Industry of Northwest Territories. By E. A. Schiller. Pp. v+62. 75 cents. Paper 65-14: Investigation of Eakers for Mineral Exploration; (2) Buried Valleys in Kirkland Lake, Ontario. By Hubert A. Lee. Pp. iii+20. 75 cents. Paper 65-20: Notes on Moraines and Radiocarbon Dates in Northwest Baffin Island, Melville Peninsula, and Northeast District of Keewatin. By B. Craig. Pp. 7. 75 cents. (Ottawa: Queen's Printer, 1965.) [1]

Cerebrovascular Accidents as a Public Health Problem—Selected Research Abstracts, II. Pp. 64. (Baltimore, Md.: Research in Public Health Administration Project, School of Hygiene and Public Health, The Johns Hopkins University, 1965.) [1]

United States Department of the Interior: Geological Survey. Geophysical Abstracts, No. 223 (August, 1965). By James W. Clarke, Dorothy Vittalano, Virginia S. Neuschel, and others. UNICAM**SP.800**

spectrophotometer
for routine U.V. analysis
with automation accessories

Save operator time, increase speed and efficiency with Unicam automation for:

ENZYME REACTION RATES

LIQUID COLUMN CHROMATOGRAPHY

**ALL ROUTINE ULTRAVIOLET AND
VISIBLE SPECTROSCOPY**

Please send for descriptive brochure

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as *the* outstanding U.V. spectrophotometer. Additionally Unicam now offers automation equipment which provides:

AUTOMATIC interchange of up to 4 sample and 4 reference cells

AUTOMATIC re-cycling over any preselected wavelength range

AUTOMATIC recordings at predetermined time intervals

Unicam Precision Spectrophotometers

HENDREY SPARK RECORDER Type 1487A

Compact and weatherproof, this single channel recorder is light in weight and easily portable. The Perspex window gives a clear view of the heat-sensitive chart for approximately 6 in. of its length.

The instrument can also be used mounted on bench, wall or panel and is supplied with mounting plate incorporating three anti-vibration mountings which render the instrument shock-proof and vibration-proof to service standards.

An electro-magnetically operated stylus, operated by a separate switch not supplied with the recorder, provides transverse markings near the edge of the chart. Provision is made for an external alarm circuit which can be pre-set to operate at any deflection from zero to full scale by means of a control on the case.

Sensitivity—50 micro-amps. Full scale. Supply—12 Volt, D.C.

IMPROVING THE CIVIL SERVICE IMAGE

ALTHOUGH the Civil Service Commission and recruitment to the Civil Service have been mentioned in recent books and pamphlets dealing with Civil Service reform, such reference has been mainly incidental and it has been left for the Estimates Committee in its sixth report for the session 1964-65* to examine recruitment to the Civil Service in any thorough fashion. Even so, the Estimates Committee was indebted to the Acton Society Trust for financing a survey of the attitudes towards an administrative career in the Civil Service of students at a civic university. As the Estimates Committee observes, this underlines the recommendation in its fifth report for this Session that it should be authorized to appoint temporary outside advisers and to obtain assistance from outside—any expenditure involved being borne on the Vote of the House of Commons. Much of the value of the report, in fact, derives not from the Committee's examination of witnesses but from the memoranda which were submitted in evidence by the Acton Society Trust and others—without whose co-operation the scope of the enquiry would have been severely restricted and its authority much diminished.

The enquiry was concerned both with the work of the Civil Service Commission and with the role of the Treasury in recruiting and with direct recruitment by other Departments. The Commission's responsibilities are now limited to the selection and certification of people for permanent posts, under regulations made by the Commissioners and approved by the Treasury. Unestablished posts are now filled by arrangements made by Departments, sometimes assisted by the Commission, and subject also to the approval of the Treasury. The Estimates Committee's recommendations are few, but the implications of the report are far-reaching: the difficulty which the Civil Service has consistently experienced since the Second World War, especially in graduate and professional recruitment, and in obtaining as many recruits as it needs, is set in the perspective of to-day's needs generally. The right questions are asked not simply about recruitment itself but about the opportunities open to recruits and the use that is made of them.

The report deals first with the pattern of recruitment, and here the figures quoted show that since 1954, while needing more recruits, the administrative class only maintained the number of assistant principals recruited and failed to maintain its share of a rapidly increasing field of possible candidates. Moreover, at a time when the fields of university recruitment were widening, the proportion of administrative class recruits from these wider fields was falling, and although until 1963 little difficulty was experienced in recruitment to the executive class, vacancies in some departmental executive classes were not being filled. In the 1964 report of the Commission, however, reference is also made to a shortage in the general executive class—the class which is broadly responsible for the wide range of managerial and administrative functions in the Civil Service and which has traditionally recruited from school-leavers with at least two passes in the Advanced Level Examinations for the General Certificate of Education.

In many respects, recruitment to the specialized classes of the Civil Service, which include the Scientific Civil Service and a range of technical and professional classes, is a lighter problem than that of recruitment to the administrative or executive classes—recruiting procedures being faster and more flexible and often undertaken by the departments. Even so, the Civil Service is at a disadvantage in the competition with other employers, even when the lengthy process of open competition, interview and certification is not needed for temporary posts. Direct appointment by establishments is not possible and Civil Service pay structures do not permit any recognition of the really first-class man on entry. Finally, scientific and technical work in the Civil Service is necessarily more organized than in the universities, which since the Second World War have been one of the main competitors for the best graduates. Certainly, there is not the same freedom of publication, though the rules concerning publication have recently been liberalized.

Of interest in this connexion are some observations on factors influencing the choice of employment in a memorandum from the Civil Service Commission. It is admitted that salaries are much more favourable to the universities than to the Civil Service compared with before the Second World War, but it is considered that attraction to the administrative class lies other than in the cash rewards. In the scientific officer class, the Civil Service has much to offer young graduates in the way of interesting work in their own field with unusually good experimental facilities and reasonable stability in the programme of work, and in general the Scientific Civil Service probably ranks second to a university appointment in the minds of good young scientists. There is, however, a tendency for the young scientist to try a period in industry. To meet this, the Service has in recent years resorted to temporary recruitment direct by departments with subsequent confirmation by the Commission when both sides have made up their minds. Nevertheless, the Commission admits that the Service does not attract as many of the really outstanding young scientists as it would like and that it is possible that this is due in part to the failure of the system of pay on entry to allow recognition of the really first-class man.

In the same context may be noticed some remarks in a memorandum from the Acton Society Trust on possible reasons why graduates from universities other than Oxford and Cambridge do not choose careers in the Civil Service. It is unlikely that the differences can be attributed to different sources of social origin in students, although this may partly explain the popularity of school teaching as a career. The nature of the recruitment process may be a hindrance, and an Acton Society Trust report on the arts graduate in industry pointed to a higher wastage among those who had been recruited into general training schemes than among those who had been recruited for specific posts. Moreover, an applicant for a career in the administrative class is really required to take on the job for the whole of his working life. This may well be a deterrent, as is also the picture of the administrative class as 'the talented amateur', overdrawn though this has always been. Nor has this yet been remedied by the reforms which have followed the Plowden Report, and the Civil Service continues to under-play the need for formal training for members of the administrative class.

* Sixth Report from the Estimates Committee together with the Minutes of the Evidence taken before Sub-Committee E and Appendices, Session 1964-65—Recruitment to the Civil Service. Pp. xxxviii+269. (London: H.M.S.O., 1965.) 26s. net.

It is at this point that the memorandum touches on the Civil Service Commission itself, which, it suggests, contributes to the present unsatisfactory image of the Civil Service through the rather negative way it handles its recruitment programme for the administrative class. Before examining that criticism of the Commission, some further points in the memorandum on the attitude of students may be noted. The exploratory enquiry conducted by the Trust indicated that some 60 per cent of science students at the University of Hull had no particular careers in mind. Most of the students thought that university teaching and school teaching were the careers most likely to offer a high degree of personal freedom in carrying out one's job, private industry and commerce getting a middle rating, followed by the Scientific Civil Service with the administrative class last. After university teaching, the Scientific Civil Service was regarded as the career most likely to offer opportunity of using the knowledge acquired in reading for a degree, and the administrative class again came last—though it was rated better as regards opportunity for easy transfer of jobs in mid-career. Moreover, except for the nationalized industries, where the opportunity was regarded as equal, between 60 and 85 per cent of the Hull students thought they stood less chance than graduates from Oxford and Cambridge, especially for the administrative class, closely followed by university teaching. More than half the students regarded working in London for the duration of their careers as a definite disadvantage; almost a third were indifferent, and only 12 per cent thought it an advantage. By far the most attractive feature of the administrative class to the students seemed to be its security of tenure, but this and other attractive features did not offset the fact that they gave it a low rating on those attributes which they held to be important in comparison with other jobs.

The extent of the knowledge of the students about the Administrative Civil Service was clearly small. The image of the Administrative Civil Servant which is based on that knowledge is a definite obstacle to recruitment and one that must be rectified. For this the present publicity techniques are inadequate and a new and more direct approach seems necessary. However, it should be noted that the Acton Society Trust thought that the facts about Civil Service recruitment were still extremely scarce and that a full-scale investigation into undergraduates' attitudes towards the Civil Service as a career should be undertaken on behalf of the Civil Service Commission as an essential pre-requisite to discussion. Meanwhile, the shortage of talented graduates and the efficiency of the Civil Service compel the Civil Service Commission to continue and increase its efforts to broaden the appeal of the administrative class. Whatever changes may be made inside the Service itself, the Commission must pursue a more aggressive recruitment policy for this class and do so imaginatively. The criticism is levelled also at the publicity of the Commission and at the university appointments boards. The latter are not so efficient as they might be; they are understaffed, and while they are often ill-equipped to give vocational guidance, for most of them, in quantitative terms, the administrative class is unimportant.

This criticism of the Civil Service Commission appears to have been accepted by the Estimates Committee. In a long memorandum on recruitment to the Civil Service, in which he also suggested that difficulties in recruitment and the like were due mainly to lack of experienced research staff and of money and could be remedied by closer collaboration between the universities, the Civil

Service and a Social Science Research Council, Prof. W. J. M. Mackenzie expressed the opinion, based on extensive personal experience, that the Civil Service Commission acts impeccably within its terms of reference. Witnesses before the Estimates Committee both from the Commission and from the Treasury conceded that change in the range of the Commission's functions had occurred in recent years, which was not envisaged in the original Order in Council, nor provided for in the Order of Council of 1956, from which the Commission derives its authority. The Estimates Committee agrees that there are strong arguments for keeping the related functions of recruitment and selection together within one agency, and believes that little would be gained by the Commission's attempting to restrict itself to the functions contained in the original Orders in Council. It did not pursue the wider question whether the final responsibility for recruiting policy and management should remain with the Treasury or whether the functions of the Commission itself should be extended, as Mr. S. Brittan suggested in his recent book*, and merely note with apparent approval Prof. Mackenzie's comment: "The problem is whether the Commission's terms of reference are right".

Prof. Mackenzie wrote his memorandum before the publication in the winter issue of *Minerva* (3, No. 2, 172/1965) of Prof. R. J. Stone's article "A Model of the Educational System", which illustrates the type of serious research and analysis which he regards as necessary in answering the questions from the Estimates Committee. He suggests, however, that two vital modern functions are now lost to view in the Victorian tradition which still appears to underlie the work of the Commission. The notion that numbers of corrupt persons are trying to insinuate themselves and their friends into the public service is archaic: in the modern world the Commission is the recruitment section of the personnel division of a large organization. If it cannot find its recruits, it must first look in a sophisticated way at the employment market and at what the organization offers to the market. If candidates of the right type cannot be found, it must report back fearlessly and constructively to the higher level. Secondly, the Civil Service is perhaps unique among lay organizations in having no public relations department, and Prof. Mackenzie suggests that the Commission cannot possibly do its job to-day unless it is able to face its competitors squarely. In his view, its function must be that of a recruitment and public relations department for the Treasury Department, which is now responsible for the personnel policy and general efficiency of the Civil Service. He regards the Commission as a well-run body, but considers that a symbolic break with the Victorian tradition might be an advantage. In this view he differs from the Fabian Group, which in 1964 proposed that personnel management should be transferred from the Treasury to a reformed Civil Service Commission strengthened by new appointments and by staff from the Treasury.

In this long memorandum, Prof. Mackenzie makes many pertinent observations and comments, of which only a few can be noted here. He pays tribute to the outstanding success of the British Civil Service in the organization and management of routine clerical work, but he does not see how its strong executive structure can be maintained except by upgrading the status and salaries of the executive class and its related departmental classes. Challenging the idea of the amateur, he points to some five respects in which the task of the administrator calls

* *The Treasury under the Tories, 1951-1964* By Samuel Brittan (Pelican Book A 722.) Pp. 375. (Penguin Books, Ltd., London, 1964.) 6s.

different types of special or professional knowledge and skill. After reminding us that the pool of really good general graduates increases much more slowly than the total output of graduates, he points to five weaknesses in present intake from the universities. The proportion of candidates with a solid first-class academic record appears to be declining; the net is not flung wide enough; while the proportion of social scientists, particularly economists, is rising, there are very few natural scientists and virtually no technologists; entrants come straight from university to service in a Department and lack training and practical experience of the world; there are few chances of varying the pattern of a career between ordinary and distinguished success, even of unofficial meeting and argument with contemporaries.

Prof. Mackenzie's comments on the scientific and professional classes offer some constructive guidance to the Commission in pursuing a realistic policy which takes account of the variations between different fields; if these comments are heeded, they could help to correct the attitude which in the mind of the Estimates Committee is responsible, as much as the general image of the Civil Service, for the poor response in the civic universities.

It appeared to the Estimates Committee that the Commission's procedures still concentrate on keeping people out rather than on attracting them. The many advantages which the Civil Service has to offer are not being communicated to the relevant audience, and the Commission has not always translated its understanding of the need for effective public relations into the most effective public relations.

So far as the Civil Service Commission is concerned, the Estimates Committee makes four specific recommendations. Alone, or in conjunction with the Treasury, the Central Office of Information or an outside agency, the Commission should examine the effectiveness of its methods of advertising and publicity. With the Treasury, the Commission should undertake a follow-up survey of executive officers, if necessary on a sampling basis, to determine the efficiency of selection methods and to isolate particular reasons for wastage in the early years of service. The Commission should also seek to quantify the categories of graduates from which entrants to the Civil Service are drawn, and the two posts at principal level recently sanctioned by the Treasury to improve contacts with teaching staff at universities should be used to improve contacts with civic universities as well as Oxford and Cambridge.

Apart from criticizing the approach of the Civil Service Commission to the whole problem of recruitment, the Estimates Committee comments at some length on its advertising and publicity, particularly in relation to the impact of recruitment for the Civil Service on the manpower situation generally—an aspect which incidentally is emphasized in the subsequent White Paper outlining the National Plan. The Committee is also critical of the liaison with both the schools and the universities, especially of the reliance on the appointments boards, the efficiency of which has been questioned both by the Acton Society Trust in its memorandum and earlier by the Heyworth Committee of the University Grants Committee which examined the work of the Boards. It is also critical of delays in selection procedure, the responsibility for which rests as much on the Civil Service as on the Commission itself. The staff side considered that the clerical class was at present losing the best potential recruits because of the time taken to recruit. Mr. B. J. Holloway, in a memorandum, pleaded for the exercise of greater imagination

and less rigidity by the Commission. He also credited the Scientific Civil Service with being the only section of the Civil Service that had really faced the problems of competitive recruitment, and pointed out that firms like Imperial Chemical Industries, Ltd., and Unilever could reach a decision in an urgent case on a first-class man in ten days from start to finish. Certainly he felt that the Civil Service could not expect to keep its candidates if it kept them waiting to the present extent.

The Estimates Committee's enquiry involves both short-term and long-term considerations, and in the latter especially are involved the whole structure of the Service and the desirability or not of radical changes in that structure. These issues are raised to some extent in Prof. Mackenzie's memorandum and even more so in one from Mr. D. N. Chester, the Warden of Nuffield College, Oxford. However, although these memoranda are interlocked with some of the questions considered here they are more conveniently considered together with related issues later. Meanwhile, it should suffice to add that, in spite of its specific criticism, the Estimates Committee is confident that the Civil Service's fine tradition of ability and integrity is still very much alive to-day. Moreover, while its structure and its public image may well need review in the light of modern needs, the Civil Service would emerge from such enquiry strengthened in public esteem and in its ability to discharge its responsibilities.

HIGHER EDUCATION AND POLITICS

Eighteen Plus

Unity and Diversity in Higher Education. Edited by Marjorie Reeves. Pp. 226. (London: Faber and Faber, Ltd., 1965.) 25s. net.

NO short account could do justice to the many thoughts expressed in this series of essays on the problems which confront the world of higher education in the post-Robbins age. In one sector of this world we are witnessing a crisis in the university more acute than that about which Sir Walter Moberly wrote. Time alone will show the extent to which this crisis can be overcome. It was perhaps one of the inevitable consequences of the Robbins philosophy that the dichotomy between institutions of higher education should be sharpened. This is diametrically opposed to what the Robbins Committee set out to achieve, namely, the integration of higher education. The removal of the colleges of advanced technology from the control first of the local authorities and then of the Department of Education and Science has put these last-named organizations on the defensive—a defensive which is now beginning to take the form of attack.

Mr. A. Crosland, the Secretary of State, in a surprisingly candid speech at the celebration of the seventy-fifth anniversary of the foundation of Woolwich Polytechnic, in April this year, has given a clear indication of Government policy, in which the thinking of the Department of Education and Science is no doubt reflected. In this speech, the text of which has been given very wide circulation, a clear distinction is drawn between the public sector of higher education, "under social control and directly responsive to social needs", and the autonomous sector, by implication oblivious to social needs. This is a harsh judgment on what the universities have accomplished in the years since the Second World War. Mr. Crosland indicated also that the Council for National Academic Awards is to be an instrument of policy in building up the public sector of higher education parallel with the development of the autonomous sector. In my view, there can be only one outcome of the attitude of mind displayed in these philosophies. We shall see, with

the passage of time, growing indignation at the iniquities of selection at eighteen plus and a growing clamour for the autonomous sector to be integrated with the public sector and brought under 'social control'. As Dr. Brian Wilson says in his chapter on the needs of students, in *Eighteen Plus: Unity and Diversity in Higher Education*, "the real issue of the times is not whether we shall have more university education but whether we shall maintain university education at all".

The sixteen contributors to this symposium write mostly on topics which have already been extensively discussed. Most of the papers were, in fact, first given at a conference in September 1963, that is, before publication of the Robbins Report. They deal with a variety of topics within the field of higher education and express many different points of view. These are linked and co-ordinated by a series of interesting commentaries by Miss Marjorie Reeves, Fellow of St. Anne's College, Oxford, who also contributes a chapter on "Prestige". This unsolved problem of the relative esteem to be accorded to different institutions and courses probably does more damage to the cause of higher education than any other single factor.

Dr. G. Templeman describes the considerations which have led to increasing concentration on single-subject degree courses and makes a plea for the enlargement of our notion of university duty so as to cover wider educational responsibilities. "Do students need an ivory tower?", asks Miss Reeves in introducing Dr. Wilson's chapter on student needs. He paints a gloomy picture of threats to university values and refers to the temptation to project an image as a substitute for building a reputation; to dilution by new types of discipline; to the increasingly professionalized attitudes of academic staff; to pressure by clientele with its demand for a qualification and a good time; and to public demand, characterized by growth, status inflation and eventual devaluation. Prof. W. R. Niblett discusses further the influence of expansion on traditional values. Prof. H. Butterfield, in a chapter on the "Springs of Intellectual Vitality", describes the infectiously stimulating atmosphere of the Cavendish Laboratory of the 1920's and what flowed from this. Several contributors refer to the present gulf between the generations which is apparently less acute in the sixth form than at the university. In her chapter on sixth-form studies, Dame Joyce Bishop deplores the stultifying influence of pressure from the universities.

Mr. J. Maitland-Edwards describes the role of technical colleges in higher education, and Miss Monica Wingate the place of the training colleges (now renamed colleges of education). Mr. B. Gowenlock deprecates the "academic rat-race" of the university of to-day. Perhaps the most significant comment is by Mr. D. Jenkins, who points out that education, like war, has now become too important to be left to the experts. This is a stimulating and challenging book which merits study by all who are interested in higher education.

JAMES COOK

FRONTIERS OF CERTAINTY

Beyond the Edge of Certainty

Essays in Contemporary Science and Philosophy. Edited by Robert G. Colodny. (University of Pittsburgh Series in the Philosophy of Science, Vol. 2.) Pp. vii+287. (Englewood Cliffs, N.J., and London: Prentice-Hall, Inc., 1965.) 70s.

BYOND the *Edge of Certainty* is a collection of essays typical of much present-day thought in regions common to philosophy and science. The reader, however, will not be wholly at ease until he recollects what in fact happened to pure mathematics in the nineteenth century. During those years the modern concept of proof was born. To some it may have seemed like an almost endless proliferation of detail: nevertheless, such a view would be

wrong. What was emerging was a deeper grasp of fundamentals, and a severe tightening of the screw as to what constitutes validity. To-day, we are witnessing something of the same kind in the realm of physics, a ruthless quest for greater rigour. The search is probably more difficult than before, if only because at some stage Nature will present her bundle of brute facts, and as we try to untie it a number of intractable items always fall out. This where the strain is greatest between those who, like Dirac, take beauty as the criterion (and indeed this is the more inspiring attitude), and those who maintain the agreement with experiment—although subject to change as technique advances—is at any moment of history the final court of appeal.

One thing is fairly clear: the progressive refinement of laboratory processes and instrumentation will not itself resolve the dilemma, since the burden of proof lies in the nature of physical law, and the way in which we tend to interpret it. Yet the whole movement is historically conditioned: cosmic physics would be nowhere without Newton and Laplace. Equally, the quantum rises majestically from the matrixes of Hamilton, and the frustration of those who clung to the pattern of continuity to explain the behaviour of radiation. As the editor of this book observes, the pressure is now for 'fine grain' and the right to question everything.

The various authors react as follows: "Newton's First Law" (Hanson) is discussed as a means of entry into natural philosophy; it is not axiomatic in the sense of being self-evident. It needs, as it were, the constant vigil of experience to support its status as a principle.

"The Origin and Nature of Newton's Laws of Motion" (Ellis) reveals their probable Cartesian origin. They can scarcely, therefore, be claimed as a product of induction from experiment: indeed, we have some latitude of choice as is shown by the possibility of constructing different principles of natural motion. In "A Response to Ellis' Conception of Newton's First Law" (Hanson) comment is made on the contrast between kinetics and dynamics—a distinction concerned with how bodies actually move compared with how they would move in certain circumstances. "A Philosopher looks at Quantum Mechanics" (Putnam) finds no satisfactory interpretation as we know the subject to-day. It may still be necessary to go on searching for hidden variables. "The Thermodynamics of Purpose" (Hawkins) is a study in natural teleology; this includes an interesting reconsideration of the green planet Earth, envisaged as a unique heat engine. "The Physics of the Large" (Morrison) looks for a compact theory of the universe, and what constitutes the units of terrestrial life. "Problems of Empiricism" (Feyerabend) is by far the longest article in the series, and leads to the conclusion that the tenet is both incomplete and contains undesirable assumptions. The former limitation is removable if the relation between man and the universe is accepted as a cosmological hypothesis. Finally, "The Ethical Dimension of Scientific Research" (Rescher) brings us face to face with those moral problems which the success of the scientific method has forced on us. It amounts to a deliberate assertion that we are responsible for our talents, and for whatever may follow from their cultivation and deployment.

F. I. G. RAWLINS

ASPECTS OF LEARNING

How and Why do we Learn?

Edited by W. R. Niblett. Pp. 196. (London: Faber and Faber, Ltd., 1965.) 21s. net.

THIS series of essays springs from a series of public lectures given at the University of London Institute of Education. Publication in book form is perhaps a good way of making some of the lectures by this very distinguished, and very mixed, group of contributors available

a wider public. But the form, which seems to be coming more popular, is itself a questionable one. Many the lecturers/authors are clearly handicapped by the limitations of time and space and one cannot help regretting that Prof. Wiseman and Prof. Morris were not able to develop their subjects more fully. Moreover, this particular collection is an extreme example of the mixture of styles and levels from which this form almost inevitably suffers. The lectures/essays fall into three marked classes: Prof. Wiseman on "Learning versus Teaching" and Prof. Morris "How does a Group Learn to Work Together" review with great learning, but necessarily in very condensed form, the latest research findings in these fields and support their views with copious references; Dr. Wall, Dr. Taylor and Dr. Kay are more concerned to put forward personal interpretations of their subjects "Learning to Think", "Learning to Live with Neighbours", and "Programmed Learning"; Miss Lee's essay on "Perception, Intuition and Insight" falls half-way between the two groups. Finally we have in Part 2 three personal essays by writers who are not professional 'educationists': Stephen Potter, Lord Caradon and Richard Hoggart.

The student who is looking for a handy summary and authoritative list of sources will probably find the first group most useful. The general reader interested in education will get little from these but much from the second group, while the third group are only marginally related to the title of the collection.

There are important points excellently made in many of the essays; for example, Dr. Wall's warning that an judicious use of visual aids may tend to fixate children at a pre-conceptual stage and make it harder for them to develop verbal symbolization; or Dr. Kay's suggestion that the next and really important development in programmed learning should come with the instruction of groups rather than individuals. If there is a theme which emerges more than others it seems to be a growing recognition of the importance to learning of relationships within the group and a diminished interest in the paradigm case of an individual in a 'learning situation'. In this respect Dr. Taylor's is one of the most interesting and certainly among the best written of the essays.

The three tail-pieces are all worth reading, though whether it was worth reprinting them in this series seems to me more doubtful. Richard Hoggart deals firmly but justly with the claim of the advertisers that they are really exceptionally honest public benefactors. Lord Caradon's analysis of the genuine concept of trusteeship is sad in its over-optimistic predictions about the future of Cyprus. But the most fascinating is Stephen Potter's revelation of how one man has learnt to enjoy so much of life. How many of us, I wonder, realized that before he turned to gamesmanship he had edited the *Nonesuch Chaucer*?

A. D. C. PETERSON

COSMIC RAY PHYSICS

Cosmic Ray Physics

By A. E. Sandström. Pp. x + 421. (Amsterdam: North-Holland Publishing Co., 1965.) 80s.

DURING the past twenty-five years a world-wide network of stations has been built up to record the intensity variations of the secondary cosmic rays reaching the surface of the Earth. The detectors comprise neutron monitors which respond to the nucleonic component of the secondary radiation and counter telescopes and ionization chambers which mainly record the mu-meson component. Information on the energy and directional dependence of the intensity variations of the primary cosmic rays far out in interplanetary space is obtained by correcting for atmospheric effects and for the deflexion of the charged particles in the geomagnetic field.

Cosmic Ray Physics, by Sandström, provides a comprehensive account of the methods used in these cosmic ray

studies and of the results found. Secondary production and cascade processes in the atmosphere are outlined, and the radiation detectors now in use are described. A detailed account is given of the statistics of particle counting with especial emphasis on the errors involved in the harmonic analysis of the daily variation in intensity. Some difficulty exists in locating the direction of anisotropies in the primary radiation due to the large opening-angles of cosmic ray telescopes and to the scattering of secondary particles in the atmosphere. Further, there is the large dispersion in the magnetic deflexion of different energy primary particles in the Earth's field. Sandström describes what is known about these optical aspects of cosmic ray telescopes.

The well-established intensity variations of the primary cosmic rays are the eleven-year cycle, inversely correlated with solar activity; the Forbush decreases in which a short-term fall of intensity by up to 15 per cent takes place and which may last for a week or more, and the diurnal variation of approximately 0.2 per cent in amplitude. There are also variations correlated with the twenty-seven-day period of solar rotation. Sandström describes the variations, in particular giving a detailed account of the different types of onset and decay of Forbush events. Various theories to explain these primary particle modulations are briefly outlined. Sandström favours the solar beam model in which plasma from the Sun streams out, carrying with it a rather regular, frozen-in magnetic field. Owing to the plasma motion a terrestrial observer also sees an electric field. Forbush decreases are interpreted in terms of particle energy-loss in the electric field together with a screening effect of the magnetic field in the beam. Some early space-probe observations are used to support this interpretation. Experimental results on the daily variation indicate a small excess of particles coming from the evening side of the Earth. Various theoretical interpretations are advanced, including the possibility that this simply represents cosmic rays co-rotating with a large-scale magnetic field, attached to the Sun, but extending far out into interplanetary space. The propagation of solar flare particles to the Earth is discussed in terms of the solar beam theory. Rather short chapters are devoted to extensive air showers, the problem of the origin of cosmic rays and the radiation trapped in the magnetosphere.

The aim of much cosmic ray work is to understand the interaction between the energetic particles, fields and plasma in interplanetary space. Direct measurements are now made of all these physical quantities using vehicles such as the *Interplanetary Monitoring Platform (IMP)* series of eccentric orbit satellites. An important early result from *IMP* is the confirmation of the idea that the interplanetary field can be roughly represented by a spiral lying in the ecliptic plane. However, the sea-level recording on which Sandström mainly concentrates yields important complementary results to the satellite work, especially with regard to the accurate measurement of small variations occurring over long periods.

The book may be recommended to undergraduates taking a special course in cosmic rays and to graduates and research workers in the field. J. J. QUENBY

SEDIMENTARY STRUCTURES

Atlas and Glossary of Primary Sedimentary Structures By F. J. Pettijohn and P. E. Potter. Pp. xv + 370 (including plates). (Berlin, Göttingen, Heidelberg and New York: Springer-Verlag, 1964.) 59 D.M.

THE first concern of all geologists is to describe logically and accurately the effects wrought by past events in the history of the Earth. Any tool that assists the professional geologist or student in training in this task is therefore to be welcomed. With their book *Atlas and*

Glossary of Primary Sedimentary Structures, Prof. F. J. Pettijohn and Prof. P. E. Potter make a notable addition to the resources of undergraduates reading earth science and of teachers in the field of soft-rock geology. The *Atlas* will also be valued by those professionals whose work lies largely outside the stratigraphical and sedimentological fields.

Most of the book is taken up with 198 photographic plates illustrating many different kinds of sedimentary structure, the majority of which are dependent on current action or on deformation of the sediment prior to lithification. Most of the plates represent natural or artificial rock-exposures, but twenty-nine come from the field of present-day sedimentary environments. The plates are preceded by a brief statement in which primary sedimentary structures are defined and classified. After the plates comes a glossary of names and terms commonly applied to sedimentary structures. The text and descriptions of the plates are also given in German, French and Spanish.

The scope of the book is a very fair measure of the advances in descriptive knowledge of sedimentary structures made since Sorby, in Britain, and Hall, in the United States, began work in this field more than a century ago. The authors' aim is descriptive and the adopted classification of structures logical within the self-imposed limitations of a field guide. Notwithstanding, a classification based on genesis of the higher ranks of structure will be regarded by many teachers as equally valid within these same limitations, on the grounds that the description and analysis of a body of rock should be so arranged as to provide the most direct path to an interpretation. Thus, for example, load casts were perhaps better illustrated with ball-and-pillow, ripple marks with cross-stratification, and current crescents with flute marks, than with the structures chosen as immediate neighbours for them in the *Atlas*.

Although the book is wide in scope there are important omissions. Aeolian dunes and related phenomena are treated very sketchily, although a wealth of photographic data exists for this important group of structures in both North America and Europe. A much fuller treatment of trace fossils could have been given without the authors having risked over-specialization. Many teachers will regret that there is no discussion of the limitations of rock-exposures as evidence of the complete form of sedimentary structures. In the case of cross-stratification, for example, surely some of the many plates used to illustrate this structure could have come from outcrops that provided more than one plane of section. Such evidence is all too rare, but because three-dimensional views are provided is to be valued the more highly.

The *Atlas* is well produced and the publishers are to be congratulated. The plates are excellent technically, if over-abundant in the case of certain structures, and the number of printer's errors is relatively small. However, it is a pity that a text is not provided in Russian, in view of the large amount of sedimentological work published by Soviet scientists in recent years. None the less, Profs. Pettijohn and Potter have performed a notable service, and their book is to be warmly recommended to teachers and students alike.

J. R. L. ALLEN

A JOURNEY THROUGH MODERN BIOCHEMISTRY

Essays in Biochemistry

Vol. 1. Edited by P. N. Campbell and G. D. Greville. Pp. xi+170. (Published for The Biochemical Society by Academic Press, London and New York, 1965.) 18s. 6d.

THE major purpose of *Essays in Biochemistry* is to provide the advanced student with an annual group of essays, less detailed than the usual specialist reviews, at a price that is within the scope of students' budgets.

In addition, the editors hope the essays will be helpful teachers and research workers as a vehicle to transport them to sectors of the biochemical front where they are not personally engaged. With the ever-increasing diversification and pace of biochemical research, the second objective seems at least as important as the first.

Volume 1 opens with an account by H. G. Wood and M. F. Utter of the role of carbon-dioxide fixation metabolism. The three main mechanisms of carbon dioxide fixation, which involve formation of carbon-carbon bonds, are described and the metabolic significance of such reactions in gluconeogenesis, fatty acid synthesis and metabolism of propionate is critically assessed. The second essay, by R. E. Davies, describes the gradual elucidation of the mechanism of muscular contraction. Although the author begins with the ancient Greeks, he rapidly progresses through the important pre-war work of R. Hill, K. Lohmann, W. A. Engelhardt and others to the massive effort which has been undertaken in the past two decades and finally to his own detailed theory. One is left with the impression that the time is ripe for a determined effort to investigate the mechanism of muscular contraction at molecular level. The important problem of determining nucleotide sequences in nucleic acids has been surveyed by K. Burton. After describing the analytical methods used for the separation and determination of fragments of nucleic acids, the author discusses enzymatic and chemical methods of degrading nucleic acids and determining the sequence of oligonucleotides. The prediction that the complete sequence of transfer ribonucleic acids will soon be known has already been vindicated by Holley *et al.* (*Science*, 147, 1462; 1965). The remaining articles on oxidative phosphorylation (D. E. Griffiths) and the photosynthetic electron transport chain in plants (R. Hill) are closely related. These are difficult subjects, both for the student and the research worker, and the authors have produced excellent accounts of them by leaving out a lot of detail and work which is of nebulous significance at the present state of our knowledge. The final article in particular is written in a refreshing style; it requires considerable courage to summarize a lifetime's work in a few pages and devote a significant proportion of the available space to indicate the problems that remain to be solved. R. Hill's account of the knowledge that accrued from his early work on haematin and haemoglobin should be an object lesson to young research workers to familiarize themselves with work that is proceeding in fields contiguous to their own.

For me, it has been a rewarding experience to journey through these carefully distilled accounts of present-day important topics to within sight of our present horizons.

D. T. ELMORE

ENGLER REVISED

Syllabus der Pflanzenfamilien

Von A. Engler. II Band: Angiospermen-Ubersicht über die Florenggebiete der Erde. Zwölfte völlig neugestaltete Auflage. Herausgegeben von Prof. Hans Melchior. Pp. 666. (Berlin-Nikolassee: Gebrüder Borntraeger, 1964.) 110 D.M.

ENGLER'S *Syllabus* has been a valued work of reference for systematic botanists since its first publication in 1892. With the appearance of the present volume covering the angiosperms the twelfth edition is completed, the volume dealing with the wide range of organisms from bacteria to gymnosperms having been published eleven years ago.

The volume has been completely rewritten by eleven contributors, the whole being edited by Prof. Hans Melchior. The numerous illustrations are all new, the old blocks having been destroyed during the Second World War. Many of the well-known, one may almost say

miliar, features of the original work are retained: the "ormation about economic and, particularly, medicinal ants, the extensive use of *Unterreihen*, and so on. There s, however, been a considerable rearrangement of the -ajor taxa, the most conspicuous feature of which is the -ansfer of the Monocotyledoneae to the end. Perhaps of -eater significance is the fact that the Pandanales, with hich the original Engler sequence of orders started, are ow placed near the end of the monocotyledons, presm -bly an acceptance of the view that the apparent sim- ilarity of their flowers is the result of reduction, not an dication of primitiveness.

In curious contrast to this is the retention of the petalous dicotyledons in the traditional order at the -eginning of that group, in spite of their syncarpous -varies and the widely held view that anemophily is a -econdary development in flowering plants. There is thus a -apparently unexplained inconsistency between the -inciples adopted for classifying the monocotyledons and the dicotyledons. This is perhaps not very important. What does seem to be of much greater importance arises -om the old, but often overlooked, question: "What is the -urpose of this classification?". The original *Syllabus* is he basis for the arrangement of many large herbaria and -umerous Floras, and so forms a guide to them; it is also o familiar to most taxonomists that when they want to ook something up they rarely need to refer to the index. The new edition has, at present, neither of these merits -nd, because of the labour involved, no large herbarium will be rearranged according to it, so it will still be neces- -ary for a working taxonomist to be familiar with the old Engler system and the Bentham and Hooker system, and -perhaps some others.

The urge to 'improve' systems of classification by -making them more 'natural' is one to which many, perhaps -most, taxonomists succumb sooner or later. It is an -understandable and perhaps laudable urge, but it seems to me unfortunate when it is given rein in a standard work of reference. In such works, for practical purposes an unchanging classification, even though rather artificial, is the most convenient. It is interesting to see that the differences between the Engler and the Bentham and Hooker systems, formerly so great, are now diminished.

In spite of this drawback, the twelfth edition of the *Syllabus* is a most valuable reference work, with its admirably clear descriptions of orders, sub-orders, families, sub-families and tribes, and the brief, but often illuminating, mention of important genera and species. It is particularly useful to have notes on pollen morphol- ogy, embryological characters and anatomical peculiar- ities included in the family descriptions. The bibliography is extensive and up to date, though perhaps rather deficient in its coverage of Russian literature. There are, inevitably, a few misprints, for example, *Astrodiscus* for *Astrodaucus* and *Bifora radicans* for *B. radians*; other- wise the book is well printed and the illustrations are clear and informative. It is certainly a work to keep near at hand.

T. G. TUTIN

PERISHABLE RICHES

Fish as Food

Edited by Georg Borgstrom. Vol. 3: Processing, Part 1. Pp. xiv+489. 125s. Vol. 4: Processing, Part 2. Pp. xiv+518. 132s. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.)

I N the preface to Volume 4 of this book the editor says that fish as food is part of the epic of mankind. But, he points out in Volume 3 that: "Only through wise utilization and efficient processing is it possible to save these extremely perishable riches of the oceans and fresh waters and place them within reach of the consuming public independent of seasons and of fishing fortunes . . .".

After death, fish deteriorates extremely quickly: even when packed with ice, biochemical changes commence immediately as indicated by the progressive accumulation of dimethylamine in the flesh. For reasons not yet under- stood calamitous breakdown of fish catches may some- times occur to produce, for example 'jellied' plaice or 'milky' hake. When environmental temperatures rise above 0° C spoilage can convert a "bin of sound fish to a soup or porridge. . . ." in 24 h.

The value of fish as food for man and its perishable nature have led from ancient times to the use of methods of preservation. Until comparatively recently, salting, drying and smoking were used. In addition to these techniques increasing use has been made since the last century of cooling and canning, and more recently of chemical additives.

No method of fish preservation is free from possible hazards. More than 4,000 years ago a Chinese wrote about the red discoloration of sea-water when it was allowed to stand and evaporate. This discoloration is due to the 'red-halophil' bacteria which can grow in high concentra- tion of salt and are the cause of the repulsive smell which sometimes develops in salted cod. Whereas most foods keep as well at temperatures up to 5° C as at 0° C, this is not the case with fish, the bacterial contaminants of which begin to flourish as soon as temperatures rise above freez- ing-point. Preservation of fish by cooling therefore re- quires special means of refrigeration.

By and large, man has been successful in preserving fish so as to allow its wide utilization as food. Fish sauces, fish pastes, marinades, anchovies and other products have become established either as essential or luxurious items in the diets of different countries. The biological mechan- isms of many traditional processing methods, and even the composition of some fish products, are not known. The techniques have evolved, not by the application of scien- tific knowledge, but from trial and error or by force of circumstance. The high cost of salt about 200 years ago, for example, probably led the people of northern Sweden and Norway to use less of it than was needed to prevent growth of bacteria. As a result fermentation occurred and, by good chance, gave a product, fermented herring, which is harmless to eat and has become prized as a delicacy.

The practice of food technology is increasing rapidly, and as it does so much new knowledge and many scientific and technical problems become apparent. This is particu- larly so in the case of fish processing; the discussions contained in the two volumes under review reveal the com- plexity of the problems and also that much is being done to try to resolve them. It is not enough to know that our forefathers preserved fish by smoking them in the house- hold chimney. On the scale that smoking of fish is now required it is necessary to know about the chemical and physical nature of smoke itself, the costs of producing it, and how temperatures in smoke kilns can be controlled. The fish sauce of Vietnam is known in France as an exotic addition to the diet. But, in a world facing catas- trophic shortage of food, the product may have much greater significance for as revealed by modern analytical techniques, it contains appreciable amounts of essential amino-acids. Until about thirty years ago the watery by- product obtained in the process of making fish meal was discarded. But the release of this waste not only caused serious pollution, but was a loss of valuable material. Fish solubles are now used as additions to animal feeds; they promote growth not only because of their vitamin content, but also because of the presence of a 'fish factor' the nature of which is unknown.

These are but one or two examples of the many topics discussed by the different authors of the two volumes, which bring to completion the treatise, *Fish as Food*. Dr. Borgstrom is to be congratulated on editing, and sub- stantially contributing to, a work which will surely remain for many years the standard exposition of the subject.

G. R. WADSWORTH

The Basic Laws of Arithmetic

Exposition of the System. By G. Frege. Translated by M. Furth. Pp. lxiii+143. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1964.) 40s.

IT is scarcely surprising that Frege's two great works, the *Grundgesetze der Arithmetik* (1884) and the two-volumed *Grundgesetze der Arithmetik* (1893, 1903), made little contemporary impression. Frege's view, that mathematical propositions are truths of pure logic, ran contrary to accepted philosophical opinions of the day; his style, partly because of the severely abstract topic, was crabbed, and his symbolism idiosyncratic. Russell's almost accidental discovery of Frege's work, and his celebrated antinomy which struck away the basis of much of Frege's elaborate construction, gave due recognition to Frege as a great pioneer in the field of mathematical logic. Mr. Furth provides a new translation of the introductory parts of the *Grundgesetze*, with the appendix in which Frege somewhat pathetically announces the receipt of the Russell paradox just as his own work was completed and sets about trying to repair the damage. An introduction of some 50 pages discusses Frege's work and explains his themes, his language and symbolism, and adds a very necessary account of the way in which certain technical terms have been translated. Frege hoped to start with a small number of logical truths and a small number of rules of inference, and thence derive all the superstructure of arithmetic and analysis. Perhaps to-day there is less interest in building the superstructure than in examining the logical foundations, and Frege's semantics and his whole philosophy of language seem more relevant to modern enquiry than his inferred consequences.

A mathematical classic has been defined as "a book which must be written but need not be read"; it may be asking too much of modern students that they should read the originals, but Mr. Furth gives them a good opportunity of understanding why books such as Frege's had to be written. T. A. A. BROADBENT

The Application of Continued Fractions and Their

Generalizations to Problems in Approximation Theory
By A. N. Khovanskii. Translated by Peter Wynn. (Library of Applied Analysis and Computational Mathematics.) Pp. xii+212. (Groningen: P. Noordhoff, Ltd., 1963.) n.p.

THIS book is written in a pleasant and easy style. It is a welcome addition to the sparse and inaccessible literature on the application of continued fractions to approximation theory. The advent of digital computers has renewed interest in this subject as in many situations it provides a more efficient form of approximation than power series or other forms. The book provides a suitable introduction to the larger and more theoretical treatise on the subject by H. S. Wall.

The first chapter (75 pages) is introductory; it describes various notations and basic concepts: convergents and the related recurrence relations, equivalence between continued fractions and power series and their transformations, convergence and its domain, and convergence tests for various forms of continued fractions.

The second chapter (75 pages) derives a continued fraction expansion for the solutions of various differential equations of the Riccati type. This leads to the expansion in continued fraction form of a comprehensive list of basic mathematical functions: binomial, trigonometric, exponential, logarithmic, hypergeometric, Bessel's, gamma functions and others.

The last two chapters describe various further techniques such as the derivation of continued fractions expansions using Cesaro summation methods and the use of matrices to describe generalized recurrence relations and their convergence. I. M. KHAZABA

Determination of pH

Theory and Practice. By Dr. Roger G. Bates. Pp. xv+435. (New York and London: John Wiley and Sons, 1964.) 100s.

THIS book is a revised and enlarged version of *Electrometric pH Determinations* by the same author. The scope of the book has been extended to include no instrumental determinations of pH and these are fully surveyed and contrasted with instrumental measurement.

The early chapters of the book are devoted to the various definitions of pH scales from theoretical and practical points of view; these are extended to par aqueous and non-aqueous systems. The treatment of the theoretical aspects is clearly stated with concise definitions of terms, symbols and conventions in accordance with the International Union of Pure and Applied Chemistry recommendations. A discussion of the choice and use of secondary standards is included in a chapter on pH standards, while the primary standards are fully defined and tabulated. The performance of primary standard solutions is usefully summarized.

Various forms of electrodes used with pH instrument are fully discussed. These include hydrogen, quinhydrone, antimony, silver/silver chloride, calomel and glass electrodes. Understandably, the various commercial electrodes and types of pH meters reviewed are mainly of American origin.

The book is concluded with a short section on the principles of automatic control using pH sensing systems. Regrettably, a number of useful tables are lost in the general text of the book; one would have expected such tables as those denoting pH values of standard buffer solutions to have been included in the appendixes. In these days of high cost books this is remarkably good value for money; it is clearly presented and readable. R. SAWYER

L'Homme Face à Son Destin

Par Charles Léopold Mayer. Pp. 251. (Paris: Éditions Marcel Rivière et Cie., 1964.) n.p.

IN this little volume the reader will find the results of a philosopher's thoughts extending over a quarter of a century. It is distinguished by its lucid French logic, combined with a certain classical inevitability of argument. There are thirty-four short chapters, and their general trend can be seen as an attempt to expose the main facets of human experience, giving due weight to both sides of a question. For example, no absolute truth can be claimed, but only relative truth, and one law to govern the universe (necessity), or failing that, the law of chance. An interesting quasi-mechanical principle is introduced, namely, that of "least irritability" which controls the behaviour of the living world much as Maupertuis's law of least action functions in dynamics. For the author, Nature is amoral, but axiological judgments belong to human beings. It may well be, too, that natural law is a useful and necessary fiction, though no less a person than Leonardo da Vinci venerated it, and in terms of it made both artistic and technical progress.

If an estimate is to be made of the value of a collection of meditations such as this, it is perhaps prudent to recommend it as an academic study, since its conclusions are significant, but not immediately applicable to the daily round and common task. Much of it is in the style of soliloquy, very attractively expressed in the French idiom. F. I. G. RAWLINS

The Thymus in Immunobiology

Structure, Function, and Role in Disease. Edited by Robert A. Good and Ann E. Gabrielsen. Pp. xxii+778. (New York and London: Hoeber Medical Division, Harper and Row, 1964.) 24.50 dollars.

THIS volume is based on the proceedings of the first International Symposium on the Thymus, and, with its contributions by 72 authors, collects together

ost of the groundwork on which our present knowledge is based. Of the 36 contributions, most are concerned with the relation of the thymus and bursa of Fabricius with lymphocytopoiesis and the development of immune responsiveness. Much of this material has been published elsewhere, and some has been reviewed also. Thus, it is pity that this book was not published more promptly after the symposium (held in 1962) when it might have had greater value.

Many of the old problems still remain: there is still no convincing evidence that the thymus, either directly or via the lymphocyte, has any trophic function on other tissues; and there is still no convincing way of determining whether thymic lymphocytes have an epidermal or mesodermal origin. However, the distinct functions of the thymus and bursa in the chicken become clearer now that thymectomy has been achieved while leaving the bursa intact.

There are lighter moments: as when one author presents the same unconvincing experiment which he first described in 1953. Another author, starting with an *idée fixe* that the thymus is concerned with growth, is continually frustrated by finding that each of his 'thymic' growth factors is a general tissue constituent. The clinical papers, though often long-winded, are perhaps the most valuable, since much of this material is not always readily accessible. Here is a fascinating collection of facts which will correct any tendency to over-simplify from the results of pure research.

There are many illustrations, which are mostly good, although the finer points of lymphoid tissue structure are not well conveyed by the usual black-and-white print. While the book will be of value in some libraries, there may be few individuals to whom it is worth the high cost.

R. B. TAYLOR

Advances in Enzyme Regulation

Vol. 2. Edited by George Weber. (Proceedings of the Second Symposium on Regulation of Enzyme Activity and Syntheses in Normal and Neoplastic Liver, held at Indiana University School of Medicine, Indianapolis, Indiana, September 30 and October 1, 1963.) Pp. xii + 405. (London and New York: Pergamon Press, 1964.) 100s. net.

THE symposia on "Regulation of Enzyme Activity and Syntheses" seem now to be established annual events, and the proceedings of the second meeting show that enzyme regulation in mammalian systems is nowadays the subject of as much research as is that of micro-organisms.

The volume, like the symposium, is arranged in six sections, each under a distinguished chairman. The first, on the regulation of gluconeogenesis, contains valuable discussions on the roles of the enzymes pyruvate carboxylase, phospho-enol-pyruvate carboxylase and fructose diphosphatase in gluconeogenesis and suggests an action of insulin as a repressor of some essential enzymes of this pathway. The second and third sections remain centred on carbohydrate metabolism and present data on acetyl-coenzyme A metabolism, the role of some steroids in gluconeogenesis, human hypoglycemia and the regulation of glucokinase. The synthesis of this last enzyme is inducible, being stimulated by glucose and by insulin.

Section four, on feed-back regulation in hepatic systems, contains papers on the enzymes lactic dehydrogenase, aspartic transcarbamylase and phosphofructokinase, on glucose regulation of enzyme synthesis and on regulation of cholesterol biosynthesis. Section five includes discussion of the substrate and coenzyme-stimulated induction of tyrosine transaminase; the final section, on enzyme regulation in hepatomata, presents studies of the variation of enzyme activities in tumours of different characteristics. Some correlation between enzyme activities, metabolic patterns and growth rates is analysed.

The volume is attractively presented, and represents a valuable progress report on a very active field of research.

C. J. R. THORNE

Seed-borne Fungi

Description of 77 Fungus Species. By J. P. Malone and A. E. Muscott. (Proceedings of the International Seed Testing Association, Vol. 29, No. 2.) Pp. 179-384. (Wageningen: Association Internationale d'Essais de Semences, 1964.) n.p.

THE authors of *Seed-borne Fungi* are well known for their experience in seed testing, and theirs is a compact and strictly practical production. After a brief historical introduction, the book contains a description of 77 species of seed-borne fungi, each illustrated by clear photographs of growth habit, fructification and/or spores, as may be appropriate to the species. The approved method of testing for its presence is indicated under each. Most of the fungi found on germinating seeds are harmless saprophytes but it is important that the tester shall be able to recognize these for what they are, and they are accordingly figured as carefully as the known parasites. The latter include 5 smuts (one, however, a common contaminant from cereal weeds) and 14 ascomycetes, or conidial states presumed to belong to ascomycetes. The 57 species in 36 genera of saprophytes described include 4 genera of ascomycetes which normally produce perithecia under test conditions, including 11 species of *Chaetomium*, 2 of *Melanospora* and 2 of *Sordaria*, all clearly figured, as well as 4 genera of phycomycetes. The fungi are arranged alphabetically, irrespective of their systematic position, often under the name of the ascus state even though only the conidial state is to be expected to appear under the test conditions. This has the awkward effect of dispersing the species of *Fusarium* described under *Fusarium*, *Gibberella* and *Griphosphaeria*, while those of *Helminthosporium* have to be sought under that name and under *Cochliobolus* and *Pyrenophora*. The treatment is not consistent, for *Batrachium cinerea* appears under that name, not as *Sclerotinia fuckeliana*, nor does *Cladosporium herbarum* masquerade under *Mycosphaerella tulasnei*, though to find *Stemphylium botryosum* we must look under *Pleospora herbarum*. Such difficulties as may arise from this treatment are resolved by an adequate index, but if one has to find a species through the index after all, the advantage of an alphabetical arrangement over a taxonomic one is lost. One feels that a taxonomic arrangement based on conidial states where they exist would be more helpful to an inexperienced worker seeking to name an unfamiliar species.

R. W. G. DENNIS

Methods for the Examination of Root Systems and Roots

By Dr. J. J. Schuurman and Dr. M. A. J. Goedewaagen. Pp. 86. (Wageningen: Centre for Agricultural Publications and Documentation, 1964.) 10.50 D.fl.; 21s.; 3 dollars.

THE underground parts of plants have been consistently neglected by botanists, most of whom have little idea how to set about investigating the morphology of a root system. This little book is therefore to be welcomed, for it describes concisely the various methods of investigation which have been used, those favoured by the authors being supported by numerous practical hints. The methods covered include the transferring of a soil monolith to a pinboard, the mapping of a profile face, the sampling of root systems by means of auger borings, and the growing of experimental plants in special containers. The scope of the book is confined to methods, and the sceptical are left to wonder whether the arduous task of disinterring roots yields a commensurate return of information. Production of the book is good; but the reader will encounter a few eccentricities of vocabulary, such as pendulum for crank handle.

W. D. CLAYTON

THE SMITHSONIAN INSTITUTION, WASHINGTON, D.C.

A COLOURFUL academic procession opened the three-day (September 16-18) celebration, marking the two-hundredth anniversary of the birth of James Smithson, founder of the Smithsonian Institution, Washington, D.C. Prof. S. Dillon Ripley, the present chief executive and secretary of the Institution, said that the bicentennial paid tribute to the Institution's past, affirmed its intent to fulfil a vital role in society, and examined the nature of knowledge and creative discovery as conceived by James Smithson and as understood to-day.

On September 16 the procession, which began with a clarion call from a tower of the world-famous red Smithsonian 'castle', included some 500 world scholars and scientists. Colonel John H. Magruder, of the U.S. Marine Corps, acted as the grand marshal, leading the distinguished gathering from the original Smithsonian Institution building across the Washington Mall, to a site near the Museum of Natural History.

Here, the President of the United States addressed the delegates in an outdoor convocation. Dr. Leonard C. Carmichael, former secretary of the Smithsonian, also gave an address, the substance of which follows.

Smithson, an English scholar, scientist, and prominent member of the Royal Society of London, left his entire estate to the United States, a country he had never seen, "to found at Washington an establishment for the increase and diffusion of knowledge among men". He died in Genoa, Italy, in 1829.

To-day, his 'legacy' comprises twelve far-reaching units:

(1) The Museum of Natural History, which has separate offices of anthropology, ecology and systematics, and departments of vertebrate and invertebrate zoology,

entomology, botany, palaeobiology, and mineral science and an oceanography programme.

(2) The Museum of History and Technology, which has departments of science and technology, arts and manufactures, civil history, and armed forces history.

(3) The National Air Museum, containing the world largest collection of historical aviation and aerospace material.

(4) The Freer Gallery of Art, specializing in near and far eastern art.

(5) The National Collection of Fine Arts.

(6) The new National Portrait Gallery, which will feature portraits and statues of men and women who have made significant contributions to the history, development and culture of the United States. This gallery will not be fully developed until 1967.

(7) The National Zoological Park.

(8) The International Exchange Service, which exchanges scientific, cultural, literary, and governmental publications with other countries.

(9) The Science Information Exchange, which receives organizes and disseminates information about scientific research in progress in the United States.

(10) The Astrophysical Observatory, located at Cambridge, Massachusetts.

(11) The Canal Zone Biological Area, a biological preserve located on Barro Colorado Island in Gatun Lake, Canal Zone.

(12) The National Gallery of Art, which has a separate Board of Trustees.

The John F. Kennedy Center for the Performing Arts, to be built soon in Washington, is also a bureau of the Smithsonian Institution, administered separately by its own Board of Trustees.

JAMES SMITHSON: PATHFINDER IN SCIENCE AND PHILANTHROPY

By DR. LEONARD CARMICHAEL

Vice-President for Research and Exploration, U.S. National Geographic Society,
and Former Secretary of the Smithsonian Institution

"Why did he do that?" Her Majesty Queen Elizabeth, the Queen Mother, asked me. I was walking with her as I showed her the Museum displays of the Smithsonian Institution. I had just said that James Smithson, the Institution's founder, was an English philanthropist who had never been on the American continent, but when he died he left his whole large fortune to found the Smithsonian in Washington.

"Why did he do that?" I had to reply that no one knew. But, as a partial answer, I would like to say something of the life of this idealistic lonely English scientist whose bequest has done so much for America and for the world and whose birth 200 years ago is now being honoured.

The basic facts of the life of this benefactor are sad and hard. H. R. Tedder, his English biographer, says he was "a man of gentle character whose life was devoted to study uncheered by domestic affection". He was the natural son of Sir Hugh Percy, first Duke of Northumberland of the third creation. This nobleman, in spite of a reputation for arrogance, was one of the great figures of his day. A contemporary called him the handsomest man in England. He had a large personal fortune and he held many posts of honour. He served as a Privy Councillor and Lord-Lieutenant of Ireland. His own family name was Smithson before it was changed to that of Percy by Parliament.

James Smithson's mother was a widowed heiress, Mrs. Elizabeth Hungerford Keate Macie, who was herself descended from King Henry VII through the line of the Dukes of Somerset. Much of his mother's considerable wealth came from her own family, the Hungerfords, and

from the estate of her deceased husband, John Macie, a country gentleman of Bath, Somerset. Her son, James, was born in France in 1765, and for this reason it was later necessary for him to be naturalized as an English subject, even though both his parents were English. Strangely, when this petition was granted by the Crown, it contained unusual provisos. It granted James the advantage of being a British subject except for certain stipulations such as that he was never to be allowed to be a member of the Privy Council or of Parliament or to be a civil or military officer. Neither could he receive any hereditaments from the Crown. Thus, unlike many scientists of his day and ours, he was never knighted.

J. C. Long, who has recently written a new life of Smithson based on extensive research in England and to whose scholarship I owe much in preparing this address, points out that these restrictions in his grant of naturalization were most extraordinary. He feels that they must have been inserted by someone with power in court circles who wished to guard against a possible political challenge later in life by this personable, wealthy, and well-born young man. Since the Duke had been a Privy Councillor, the specific mention of this office as barred to his natural son may not be without significance in hinting at the author of the surprising prohibitions. Many facts about Smithson's life are in doubt and may always remain so, because his personal papers, which were sent to America when his Institution was founded, were lost in the disastrous Smithsonian fire of 1865. Two hundred of Smithson's unpublished manuscripts and thousands of items of his personal memorabilia and his mineral collection of some ten thousand specimens perished at that time.

Fig. 2. Museum of History and Technology, Smithsonian Institution

In 1782, at the age of seventeen, James matriculated at Pembroke College, Oxford. Here, because of his family, he wore the special gown and had the privileges of a 'gentleman commoner'. On matriculation he signed the thirty-nine articles of the Church of England, and throughout his life he remained loyal and constant in his membership in this church. This was true even during the extensive periods of his life which were spent on the Continent of Europe.

James mastered well the regular classical studies of his period at Oxford. Almost from the first, however, he became interested in the then extra-curricular activity of the study of experimental science. Soon he was recognized as one of the leading authorities at Oxford in the infant science of chemistry. He also became an intensive student of geology and mineralogy. While still an undergraduate he was a scientific member of an important and well-organized geological expedition under the direction of a distinguished French mineralogist.

At twenty-one years of age, in 1786, he graduated with the degree of master of arts. His already achieved distinction as a chemist is attested by the fact that eleven months after he received his degree he was elected a Fellow of the Royal Society. He seems to be the youngest man ever to have received this honour. The Royal Society, then as now, was recognized as having no peer among the learned academies of the world. It is indeed amazing to think of a scientist of twenty-two being able to write after his name the great letters, F.R.S.

He soon established himself as an almost-official helper and close colleague of Henry Cavendish, the discoverer of hydrogen and one of the most distinguished scientists of the eighteenth century. This scholarly man, son of Lord Charles Cavendish and grandson of the Duke of Devonshire, was the possessor of a large personal fortune, but he elected to live almost a hermit's life and to develop the excellent private laboratory in which Smithson worked with so much satisfaction.

James Macie, as Smithson was known at that time, also established close friendships with other scientists in London and especially with Sir Joseph Banks, president of the Royal Society. Other friends were Sir Humphry Davy and the American-born Benjamin Thompson, Count Rumford.

Before his mother's death she expressed the wish that her son adopt the name Smithson, his father's family name. As I have noted, his father had taken the name Percy when he was created Duke of Northumberland. It is interesting that Smithson's mother and also Sir Hugh's wife were related by blood to the Percy family, but the Duke himself was not. In 1801 the petition for his change of name was granted, and thereafter the founder of the Institution is officially James Smithson.

As a young scientist Smithson was assiduous in attending meetings of the Royal Society and was active in his own programme of experimental research. He soon began the publication of important scientific papers. To-day we hear of the so-called 'publish or perish' policy of some large universities. Smithson would have passed this test with honour. In all he published some twenty-seven papers in the most respected scientific research journals of his day.

Smithson never married, and in spite of the gay world into which he was born and his ample fortune he devoted his life to study and research. Not only was he active in scientific associations but he also visited and worked with leading research men of his day in Berlin, Paris, Rome, Florence, Genoa, and Geneva. He knew France well under the monarchy, but when anti-Royalist sentiments became common in Paris he found himself sympathetic with them. Indeed, all his life he was philosophically favourable to a republican form of government rather than to a monarchistic one, but he deeply disapproved of the excesses of the French Revolution. He did, however, understand its basis in the errors of the old régime. He wrote in this

connexion: "Stupidity and guilt have had a long reign and it begins indeed to be the time for justice and common sense to have their term".

No one knows how close Smithson was to his autocratic, handsome, and politically powerful father, the Duke of Northumberland, or to the Duke's other children who were his half-brothers and -sisters. It is interesting that one of his half-brothers, Earl Percy, who later succeeded his father as Duke of Northumberland, was Lieutenant-General of the British forces during the American Revolution. He led British troops back from the battle of Lexington and Concord. He secured his recall from America because he had long disapproved of the policy of George III towards the colonies. General Percy, indeed like James Smithson and some other members of his family, was a very moderate Tory and much attracted to republican theories. He was known as an admirable landlord and as a most generous officer by those under his command. How much these attitudes and especially his view of America influenced his younger half-brother, James, we probably will never know.

James Smithson was disturbed by the success of Napoleon in Europe, but he continued to visit the Continent for study and research. In 1807, he was seized as a prisoner of war by the Napoleonic authorities as he was about to sail back to England from Denmark. His treatment as a prisoner was harsh, and he never fully recovered from the chest illness which he acquired at this time. Almost certainly as a result of the intervention of his friend Sir Joseph Banks of the Royal Society, the King of Denmark interceded on behalf of Smithson. Even with this help, although his lot was brightened, he did not succeed in returning to England until Napoleon's power waned after the disastrous Russian campaign of 1812.

In 1800 and 1801, before these difficult prison years, Smithson had been one of the group which established in London the Royal Institution. This new organization had and has a remarkable mission which in many ways suggests the purposes of Smithson's own later institution in Washington. The purpose of the Royal Institution as set forth in its charter is:

"For diffusing the knowledge and facilitating the general introduction of useful mechanical inventions . . . and for teaching by courses of philosophical lectures and experiments the application of science to the common purposes of life."

As I have already stated, most of Smithson's own scientific work dealt with chemistry or mineralogy and with what would now be called applied science. One of his most notable contributions was his development by the ingenious use of the still-primitive chemical methods available of the basic distinction between the native carbonates and silicates of zinc. As a result of this work the beautiful and economically important zinc carbonate ore is now called 'smithsonite'. One of Smithson's real memorials at his Institution in Washington is a specially constructed case in which various forms of brilliantly coloured smithsonite slowly revolve on a turntable so that each year hundreds of thousands of visitors to the Institution's Hall of Minerals and Gems can see the full beauty of the founder's great mineral.

Smithson also was one of the pioneers in what is to-day called microchemistry. He was able to analyse quite minute quantities. On one occasion he effectively identified the salts in solution of half a drop secretion from a human lacrimal gland. He also developed a method for the detection of very minute quantities of arsenic and mercury.

In spite of his concern with experimentation he was also interested in the theory and philosophy of science. One of his papers deals in an effective way with the errors of a contemporary scientist who tried to see unjustifiable biblical significance in fossil bones collected in a Yorkshire cave.

Smithson was well aware of the insufficiency of scientific knowledge of his time. He said: "What we know in

mistery bears so small a proportion to what we are ignorant of; our knowledge in every department of it is so incomplete, consisting so entirely of isolated points, thinly scattered, like lurid specks on a vast field of darkness, that researches can be undertaken without producing some results leading to consequences which extend beyond the boundaries of their immediate object".

He was also far ahead of his time in concerning himself with the fundamentals of scientific research and scientific method. At one point he wrote in adumbration of much later knowledge: "The particle and the planet are subject to the same laws, and what is learned of one will be known of the other".

The eighteenth century was not a period noted for great personal morality on the part of many members of its wealthy and influential families; but no breath of scandal, even by surmise, has attached itself to James Smithson. It may be noted, however, that he did have one form of recreation that may call for the raising of at least some proper modern eyebrows. He liked to gamble. He was well known in the casinos of European capitals. But Smithson was a good mathematician, and he early convinced himself that the only consistent winner in a gambling hall was the proprietor. He even calculated with care what such a man's winnings were apt to be. Because of this knowledge he always limited his expenditures at the table of chance to a predetermined sum which was well within his means for an evening's entertainment.

Three years before his death Smithson wrote his famous will. It began as follows: "I James Smithson Son to Hugh, 1st Duke of Northumberland, and Elizabeth, Heiress of the Hungerfords of Studley, and Niece to Charles the 4th Duke of Somerset, . . . make this my last Will and testament. . .". The Will provided that the income of his estate should go to his nephew, and if the nephew later had children the principal should go to them. But if his nephew should die without heirs he bequeathed the whole of his property, "to the United States of America to found in Washington under the name of the Smithsonian Institution an establishment for the increase and diffusion of knowledge among men".

On June 26, 1829, Smithson died in Genoa, Italy. In this city he had close scientific colleagues. He had been a devout attendant at the Church of England services in that city, and it was after services in this church that he was buried in the Protestant cemetery of that city. To-day there is in the English Church of the Holy Ghost at Genoa a fine marble relief monument to Smithson erected by the Regents of the Smithsonian Institution.

His nephew died without heir on June 5, 1835, and even weeks later President Andrew Jackson in an address to Congress made formal recognition of the gift to the American nation.

After prolonged discussion and largely as a result of the effective work of John Quincy Adams, who had returned to the House of Representatives after his period as President of the United States, an act authorizing the Smithsonian Institution was passed by the Congress and signed by President Polk on August 10, 1846. The English gold sovereigns in which the bequest was paid were brought to America and recoined at the Philadelphia Mint. In new American money the bequest was 508,418.46 dollars.

The bequest may not seem very great to-day, but at that time it was correctly recognized as a most significant sum. No comparable amount of money then existed in America in any university or other establishment to be used as an endowment to support research or the diffusion of knowledge.

Under the administration of the first Smithsonian secretary, the distinguished scientist Joseph Henry, and with the support of an able Board of Regents, the Institution was soon actively engaged in its work of fostering new scientific research. Through the years Smithson's phrase, "the diffusion of knowledge", has been interpreted at his

Institution to mean the issuing of books and monographs and the development of truly instructive museum displays. At least 12,000 separate publications have been issued by the Smithsonian Institution.

At about the turn of the century word was received that land changes were threatening the area of the cemetery in which Smithson was buried in Genoa. The Regents of the Smithsonian delegated their very distinguished member, the great telephone inventor, Alexander Graham Bell, to go to Genoa and investigate the condition of the founder's grave. As a result it was decided that Smithson's remains should be brought to Washington. His marble sarcophagus was transported with honour to the United States, and borne from the Washington Navy Yard to the Institution, accompanied by a troop of cavalry, a detachment of Marines, and the Marine Band. To-day, under English and American flags, the sarcophagus rests in a beautiful chapel in the Institution's original building on the Mall here in Washington.

So, as we think of Smithson's quiet and useful years and of his amazing gift to the United States, we can again consider the Queen Mother's query: "Why did he do that?" Still it must be said no one can answer this question with assurance, but I hope some people may feel with me that an understanding of Smithson's life makes it apparent that he was a prudent but true son of the 'Enlightenment'. In youthful and active America he saw much that was hopeful for the human race everywhere. His own Institution has certainly been true to his ringing charge, and in each year since its founding it has transformed some good aspect of his dream into solid serviceable reality.

When the Smithsonian was established, Washington was a swampy and fever-ridden community of some 5,000 people, and the country of which it was the capital had scarcely begun the kind of scientific research which even then was providing much humanly important, pure and applied knowledge in the older European countries. The careful handling of the income from Smithson's bequest and of funds provided by other gifts, and above all by appropriations of the Congress of the United States, has allowed the Smithsonian Institution through the years to serve as a pioneer in the establishment of the great scientific tradition of the United States. To-day and indeed through all its years, the success of the Smithsonian has been due in large part to the devotion of its always-eminent and always diligent Board of Regents.

The utterly unselfish generosity and the broad and wise terms of Smithson's bequest aroused great interest in the United States and indeed in the world when it became known. In many ways this unprecedented gift still helps set a pattern for charitable and educational benefactions. Histories of the development of the great philanthropic foundations of the United States which are doing and have done so much for the world rightly begin with a reference to James Smithson's beneficence.

As a man Smithson was a loyal son of England. But as a scientist his horizon always was global. He once wrote: "The man of science is of no country, the world is his country, all mankind his countrymen". Surely those of us who have been privileged to know Smithson's Institution intimately cannot help feeling that by his gift he established an Institution which certainly in the future, as in the past, will continue the great work of the increase and diffusion of knowledge in a way that will benefit all mankind everywhere.

It is well that the following words of Smithson himself are cut in the stone of the Institution's great new Museum of History and Technology:

"Every man is a valuable member of society who, by his observations, researches, and experiments, procures knowledge for men . . . it is in his knowledge that man has found his greatness and his happiness, the high superiority which he holds over the other animals who inhabit the earth with him, and consequently no ignorance is probably without loss to him, no error without evil. . . ."

Such a "valuable member of society" indeed was James Smithson, the sagacious, far-sighted and truly philanthropic founder of the now honoured and superlatively useful Smithsonian Institution.

SCHOLARLY SESSIONS AT THE SMITHSONIAN BICENTENNIAL CELEBRATIONS

The following sessions were held during September 17-18. The chairman is named (in brackets) followed by the speakers.

(1) *Man's Origin and Progress* (Dr. Caryl P. Haskins, president of the Carnegie Institution and regent of the Smithsonian Institution): Prof. F. L. Whipple, director of the Smithsonian Astrophysical Observatory; Prof. Claude Levi-Strauss, director of the Institute of Ethnology, University of Paris.

(2) *Environmental Influences on Man* (Dr. Crawford H. Greenewalt, chairman of the Board, E. I. du Pont de Nemours and Co., and regent of the Smithsonian Institution): Dr. Ian McTaggart Cowan, dean of the faculty of graduate studies, University of British Columbia; Prof. J. Robert Oppenheimer, professor of physics and director of the Institute of Advanced Study, Princeton, formerly director of the Los Alamos Scientific Laboratory.

(3) *Man and Technology* (The Hon. A. M. Burden, former American Ambassador to Belgium and regent of the Smithsonian Institution): Prof. Herbert Butterfield, master of Peterhouse and professor of modern history in the University of Cambridge; Dr. Lewis Mumford, president of the American Academy of Arts and Letters.

(4) *Inheritance, Values and Creativity* (The Hon. John Nicholas Brown, former assistant secretary of the U.S. Navy for Air and regent of the Smithsonian Institution): Prof. G. Evelyn Hutchinson, Sterling professor of zoology, Yale University; Sir Kenneth Clark, former director of the National Gallery, London; Mr. Arthur Koestler, author.

(5) *Man's Developing Intellect and Attitudes*: George H. Mahon, United States Representative (Te and regent of the Smithsonian Institution); Prof. Jer-S. Bruner, professor of psychology and director of Center for Cognitive Studies, Harvard University; Prof. Stephen E. Toulmin, professor of the history ideas and philosophy, Brandeis University, former director of the Nuffield Foundation Unit for the History of Ideas in London.

JAMES SMITHSON MEDAL: ROYAL SOCIETY OF LONDON

The James Smithson Medal, instituted in memory of British founder of the Smithsonian Institution, is award for distinguished contributions to "the increase and diffusion of knowledge among men", the role of Institution as set forth by James Smithson in making bequest of his fortune to the United States.

The Medal is the creation of Paul Vincze of London following closely a medallion made in 1817 by the well-known sculptor and engraver at the Paris Mint, Nicolas Pierre Tiolier, which was marked on the back in Smithson's own hand as "my likeness". Vincze has created on the obverse a portrait of James Smithson, surrounded by his name and dates of his birth and death, 1765-1829. The reverse bears a rendering of the familiar outline of the first Smithsonian building, for which the cornerstone was laid on the Mall on May 1, 1847.

The Medal was presented for the first time on September 18, 1965, to the Royal Society of London, during the bicentennial celebration. In the future it will be presented for exceptional achievement in the various disciplines of science and the humanities embraced by the Smithsonian Institution.

The first Smithson Medal for outstanding contribution in the fields of science, technology, history, and art was presented by Robert V. Fleming, chairman of the Board of Regents of the Smithsonian Institution.

EVOLUTION IN THE BIOSPHERE

By PROF. HAROLD F. BLUM*

National Cancer Institute, National Institutes of Health, Bethesda, and Department of Biology, Princeton University

EVOLUTION in the biosphere—whether biological or cultural—is based on the persistence of patterns which are on occasion subject to alteration, the altered pattern persisting in turn until another alteration occurs. The genotype pattern of a species persists through replication in the germ cells from generation to generation, subject to rare modification which constitutes mutation. Cultural patterns are also perpetuated; we do not know much about the mechanism in this case; but it is clear that they may persist for long periods although readily modifiable when circumstances arise¹.

Perpetuation makes possible the selection of some patterns—according to the dictates of environment or other factors—with the consequent rejection of others, for example, the natural selection of a mutant form from a number of possible alternatives. By restricting our view to the selected patterns and disregarding the rejections we see evolution as an increase in order, although the order is related inversely to the number of rejections. We may picture the increase in order in the evolving system as accompanying the addition of facets of pattern to the pattern as a whole; somewhat analogous to increase in order with growth of a crystal. Since change in pattern is relative to existing pattern, the number of facets may be expected to grow exponentially; thus

increase in order is accompanied by limitation of subsequent change to a general type of pattern, but at the same time the possibilities of change within the scope of that pattern may increase.

Analogy may be made to a computer, where the number of possible answers is decreased by selection of one answer instead of another, each question being postulated on the previous one². The increase in order of the evolving system should, then, be expressible in a form similar to that applied to computer operation:

$$-\Delta s = q \ln \frac{f_2}{f_1} \quad (1)$$

where $-\Delta s$ is the negentropy change, f is the number of facets of biological or cultural pattern in the evolving system, q is a constant, and \ln indicates the natural logarithm. Successful mutations and adopted cultural innovations represent additions of facets to respective existing patterns.

Perpetuation of both genetic and cultural patterns depends on perpetuation of the kinds of organisms which carry them. This involves maintenance as well as reproduction, paid for in terms of free energy amounting to about 2×10^{18} kg cal/yr captured from sunlight by photochemical reduction of carbon dioxide. The fraction of the total free energy expenditure which supports the

* Present address P.O. Box 704, Princeton, New Jersey, U.S.A.

rection of changes in pattern directly concerned in the increase of negentropy must be extremely small, so no violation of the second law of thermodynamics need be feared in the increase of order which accompanies evolution.

Although the supply of free energy limits the rate of accumulation of negentropy, it does not control the direction in which evolution may take, any more than the amount of electrical energy supplied to a computer influences the answers it gives to questions. Thus, although the biosphere is ultimately dependent on the Sun for its supply of energy, the course of evolution may be treated as virtually independent of events in, and properties of, the universe beyond Earth's limits. Some influence from outside our planet must, of course, be admitted—the rate of occurrence of mutations may be influenced by ionizing radiation from external sources, and investigation of the heavens has played a profound part in Man's cultural evolution—but we may neglect these as minor factors in our view of the process as a whole.

Evolution in the biosphere does not constitute movement toward greater order *per se*; but is guided by changes in specific properties, as contrasted with changes in number of arrangements of properties in terms of which change in order is measured, and these two things need not run closely parallel. (May we not think of free energy depending on specific arrangements of microscopic properties, as contrasted to the number of arrangements of microscopic properties in terms of which entropy is measured?) For example, natural selection of a mutant over a parent form depends on specific properties of the two phenotypes and on specific properties of the environment with which they impinge—the resulting change in the genotype pattern entails, but does not depend on, a change in order.

Whether dealing with computer operation or with evolution, the assumption is usually tacit that increase in order is accompanied by increase in meaning², which must presumably be defined in terms of specific properties. Even though we might conceive of measuring meaning in terms of all the specific properties of the system, we would still not know how to fit our measurements into the same dimensional framework with the number of facets of orderly pattern. In practice we assess meaning in terms of subjective judgments (although sometimes this is concealed), thus substituting attributed meaning for the true meaning we cannot hope to measure; this would seem a potential source of error in thinking about the evolution of living systems.

It may be useful to formalize this situation by assuming quantitative relationship between attributed meaning, true meaning, and orderly arrangement of facets, representing this by:

$$x' \ln \frac{m'_2}{m'_1} = x \ln \frac{m_2}{m_1} = q \ln \frac{f_2}{f_1} \quad (2)$$

where m is a quantitative measure of true meaning, m' a measure of attributed meaning, and x and x' are respective constants which we imagine can be related to each other and to q within a common dimensional framework, although knowing that this cannot really be done.

Exponential growth of each of the variables, m' , m and f , expressed in equation (2), may be rationalized on the basis that change in pattern is always relative to existing pattern, whether involving change in number of facets or specific change in properties, and that our subjective estimates presumably follow the latter in a general way. Thus, in whatever terms measured, the addition of each facet increases the possibility of expansion of the pattern. We may, for example, expect culture to evolve exponentially because usually each cultural innovation increases the chance of further innovations³; even when there may be loss of facets, this should be relative to the existing pattern.

Evolution of the biosphere may be thought of as composed of many interplaying parts, and equation (2) may be applied to the whole or to a single one. In practice, our attention is usually focused on a particular part, say the species of a given genus or a single aspect of culture, which it is convenient to treat as a separate system independently of the whole. In so doing, however, we should not lose sight of the possible effects of other parts on the one we study, but we cannot expect to fit x' and x for different parts into the same dimensional framework.

The changes in specific properties which may be regarded as steps in evolution—successful mutations, and cultural innovations—may be thought of as chance events distributed successively in time. But since any given step depends on an existing pattern, the probability of the step occurring must be relative to the existing pattern, and hence not to be treated as a strictly random happening. Thus, the rate of evolution cannot be regarded as completely independent of the pattern of the evolving system, but for purposes of description we may write:

$$x' \ln \frac{m'_2}{m'_1} = \int_{t_1}^{t_2} f(t) dt \quad (3)$$

where $f(t)$ is a function which may take a variety of shapes; the equation is written for attributed meaning since it is this we perforce investigate.

In the simplest form equation (3) might take, $f(t)$ would be a constant, α :

$$x' \ln \frac{m'_2}{m'_1} = \alpha t \quad (4)$$

Equation (4) should be thought to hold in only a statistical sense, since it is unlikely that all evolutionary steps can be given equal weight or that they occur at regular intervals of time, as the equation might imply. Such simple exponential growth seems fairly closely followed, nevertheless, in some instances, by various aspects of cultural evolution for short periods of time³, and by number of species of molluscs⁴. But it would seem impossible that a curve of this form could be followed indefinitely, evolution being eventually restricted for various reasons; for example, increasing adaptation to an ecological niche would seem to impose restrictions on evolution of the given species, development of one aspect of culture may place restrictions on another, and the size of the system must itself impose limits.

If we assume that the probability of selecting new facets of pattern falls off exponentially with time due to such restriction, we may write as a general expression:

$$x' \ln \frac{m'_2}{m'_1} = \beta(1 - e^{-\gamma t}) \quad (5)$$

where β and γ are constants, and e indicates the base of natural logarithms.

Curves described by equation (4) may represent early parts of curves described by equation (5), since for small values of t the function $(1 - e^{-\gamma t})$ is very nearly equal to γt . On the other hand, for large values of t the function approaches unity, thus describing approach to a static condition, as may be exemplified in the brachiopods and in *Sphenodon*, where there has been little evolution for very long periods of time. In a preliminary search I have not found many data on biological evolution which seem appropriate for such analysis. On the other hand, aspects of cultural evolution often indicate relative growth; some curves approach a limit after the manner of equation (5), others follow equation (4) more or less closely, but sometimes show fluctuations which suggest acceleration and deceleration of relative growth. It is proposed to discuss elsewhere a variety of curves describing aspects of cultural evolution, among which there may seem little similarity at first glance; but which may be reasonably well fitted by equation (3) when simple, logical forms are

assigned to $f(t)$. All this suggests that evolution follows variations on an exponential theme, and may be thought of as a relative growth process.

Let us imagine, for purposes of contrast, an environment with a fixed number of ecological niches each one of which can best be filled by a species having a specific inherited pattern. Then, given adequate time, all species with inherited patterns that do not fit best will be eliminated, leaving every niche perfectly filled. In this kind of panglossian world, where everything happens for the best if one waits long enough, evolution might be expected to follow a more or less linear course, and to have only one ultimate outcome. One wonders at times whether some such a world is not tacitly assumed in a good deal of present thinking⁵. Recent achievements in biochemistry indicating nice evolutionary series of molecular structure may have encouraged this thinking⁶: but such series are, of course, to be expected if evolution follows a course of relative growth.

If one adopts the idea that each chance step in evolution can only be taken in terms of an existing pattern—which seems imposed by modern concepts of genetics—one admits the possibility that evolution in another biosphere than ours might, although starting from nearly identical initial conditions, arrive at an array of species and cultures widely different from those we know, or even none what-

soever. Only by tacitly disregarding the possible alternate pathways open each time a facet of pattern was selected does one arrive at the notion of inevitableness in evolution; yet selection from among alternate pathways is essence of Darwinian theory.

I thank Prof. Roger S. Pinkham for his advice.

Note added in proof. After writing this article, one Sir Karl Popper has appeared (*Nature*, 207, 233; 1965) which has been taken by at least one reader to suggest that evolution in the biosphere runs counter to the second law of thermodynamics. (My book, *Time's Arrow & Evolution*, Princeton Univ. Press, 1951, revised printing Harpers, 1962, is wrongly cited there, which may be confusing to a reader wishing to examine the original statements referred to.) In both this and another recent paper (*Nature*, 206, 131; 1965) it is pointed out that a thermodynamic balance sheet cannot be drawn up for evolution in the biosphere, because the dimensions of the system cannot be properly evaluated; but there seems no reason to assume that the second law is disobeyed.

NEWS and VIEWS

Pacific Science Center Foundation Arches of Science Award : Dr. Warren Weaver

DR. WARREN WEAVER has been elected to receive the Arches of Science Award of the Pacific Science Center Foundation. This comprises a cash prize of 25,000 dollars and a gold medal. It will be presented to Dr. Weaver at the Pacific Science Center on October 25. The Arches of Science Award is presented to an American who has made "the outstanding contribution to the public understanding of the meaning of science to contemporary man". The first recipient of the Award, Dr. Weaver is well known as a 'communicator of science', and is recognized as one of the outstanding public interpreters of the scientific revolution of the past half-century. Associated with the Rockefeller and Sloan Foundations for more than thirty years, he is also an internationally known mathematician, administrator of some of the leading scientific research institutions in the United States, an author, editor and lecturer. In announcing the Award, Dr. Edward E. Carlson, president of the Pacific Science Center Foundation, said: "Dr. Weaver's selection for this new Arches of Science Award adds prestige comparable to the highest prizes for science achievement. The scientific community, because of their regard for Warren Weaver, is characterizing the Award as an American Nobel Prize—and it is significant that more than fifteen Nobel Laureates in science have received Dr. Weaver's early recognition and support".

During his response to the announcement of the Award, Dr. Weaver said: "Most of the previous significant rewards for scientists have been given exclusively for what the individual has done inside of science, strictly for notable contributions to scientific research. Individuals who can make such contributions clearly deserve society's highest honours. But the relations of science to society, to our total culture, and incidentally to our government, are now quite unlike what they were even twenty-five years ago. It is essential that we to-day have individuals who are capable of understanding science, and who are willing to live their lives partly within science but also partly within the world of affairs. These persons, working at the interface of science and society, are more than

useful—they have become essential". Sponsor of the Award is the Pacific Science Center Foundation of Seattle, Washington. The Foundation is a non-profit agency composed of business, scientific and educational leaders: the Pacific north-west who have been joined by leaders of science throughout the nation to create an active and permanent centre dedicated to increasing the public understanding of science. The Foundation operates the Pacific Science Center which was the popular U.S. Science Exhibit at the Seattle World's Fair of 1962. The Arches of Science Award was named for the five instantly recognizable arches soaring into the sky above the Pacific Science Center. The arches have become symbols of the technological strides and superior climate for science and science understanding emerging from the Pacific north west.

New Zealand Department of Scientific and Industrial Research : Dr. K. A. Wodzicki

DR. K. A. WODZICKI, director of the Animal Ecology Division of the New Zealand Department of Scientific and Industrial Research, retired recently after holding the position for sixteen years. Dr. Wodzicki was born in Poland and educated at the University of Cracow where he completed his M.Sc. and Ph.D. degrees. After serving as a lecturer at this University he was later appointed professor of animal physiology at the University of Warsaw, where his research work was concerned mainly with the genetical and ecological aspects of birds and animals. At the outbreak of the Second World War he escaped to France where he joined the Polish Government in Exile, and in 1941 was appointed as its Consul-General in New Zealand. In 1946 he was employed by the Department of Scientific and Industrial Research to survey the wild-life problems in New Zealand, and following the preparation of his report—which was later issued as a Departmental *Bulletin*—it was decided to set up an Animal Ecology Section of the Department with Dr. Wodzicki as officer in charge. Under Dr. Wodzicki's direction the Section has undertaken basic research on the ecology and physiology of introduced small animals, such as rabbit, hare and the mustelid family, and of birds such as

s. Dr. Wodzicki made a special study of the gannets in their nest at Cape Kidnappers, Hawke's Bay. This study is recognized by ornithologists as one of the most rewarding of its type carried out anywhere, and has produced a great deal of new information about this bird.

Dr. J. A. Gibb

DR. J. A. GIBB, who will succeed Dr. Wodzicki as director of the Animal Ecology Division of the Department of Scientific and Industrial Research, was born in Dorset, England, and educated at Sherborne School and at the University of Oxford, where he gained his M.A. and Phil. in zoology for research work on bird and insect populations carried out at the Edward Grey Institute. During the Second World War he served with the Royal Artillery in the Mediterranean Sector. Dr. Gibb joined the New Zealand Department of Scientific and Industrial Research in October 1957 as an animal ecologist, and was in charge of the Division's major research project in habitat ecology concerned with a study of population dynamics and feeding behaviour. In 1963 Dr. Gibb visited the United Kingdom and the United States to attend a meeting of the British Ecological Society and to visit various research institutions; in 1964 he visited Australia to attend a conference on "Vermin Control".

Mr. E. W. Hullett

MR. E. W. HULLETT has retired as director of the Wheat Research Institute of the New Zealand Department of Scientific and Industrial Research. Mr. Hullett went to the University of Canterbury (New Zealand), where he gained his M.Sc. degree with honours in chemistry. He was later awarded a National Research fellowship for study overseas, and on return to New Zealand became lecturer at Lincoln College before joining the staff of the Wheat Research Institute in 1934; in 1936 he was appointed chief cereal chemist, and in 1950 succeeded Dr. O. Frankel as director of the Institute. Mr. Hullett is specialized in cereal chemistry and its application to milling and baking techniques, and under his directorship the milling and baking industries have benefited greatly from the research undertaken and the testing and information services provided by the Institute.

Mr. R. W. Cawley

MR. R. W. CAWLEY has been appointed director of the Wheat Research Institute in succession to Mr. E. W. Hullett. Mr. Cawley graduated M.Sc. with honours in chemistry from Auckland University College in 1948. After lecturing for two years at Massey University, Palmerston North, he was appointed to the staff of the Wheat Research Institute as assistant chemist in 1950. His research work has been concerned with cereal biochemistry, particularly with the process of dough fermentation. In 1963 he was granted a research fellowship at the Wheat Research Unit of the Commonwealth Scientific and Industrial Research Organization, Australia, where he made a special study of pentosans, and their role in bread-making.

Mr. N. Modriniak

MR. N. MODRINIAK has retired from the position of superintendent of the Geophysical Survey, Geophysics Division, New Zealand Department of Scientific and Industrial Research. Mr. Modriniak, who was educated at Leoben, Austria, arrived in New Zealand in 1927 and was engaged on geophysical prospecting with private companies for the following six years. In 1933 he joined the New Zealand Department of Scientific and Industrial Research, and until the outbreak of the Second World War he was concerned mainly with prospecting alluvial deposits for gold. In this period he pioneered the use in New Zealand of seismic methods for the investigation of shallow structures. Mr. Modriniak was among the first

to become interested in the possibility of deriving power from geothermal steam in New Zealand, and the exploration of geothermal resources led to a major expansion of the Geophysical Survey in the late 1940s. During the early 1950s, when interest in and optimism about New Zealand's oil resources were at a low ebb, Mr. Modriniak persevered with seismic reflexion tests in the major sedimentary basins with the view of stimulating the interest of the major oil companies. While geothermal power, engineering and oil have been the main concerns of Mr. Modriniak as a Government scientist, he has always been actively interested in the fundamental geophysical structure of New Zealand and the south-west Pacific region generally.

Dr. T. Hatherton, O.B.E.

DR. T. HATHERTON has been appointed to succeed Mr. N. Modriniak as superintendent of the Geophysical Survey, Geophysics Division, New Zealand Department of Scientific and Industrial Research. Dr. Hatherton was born in Yorkshire and received his education at Normanton Grammar School and the Universities of Birmingham and London. In 1950 he became the first United Kingdom recipient of a New Zealand National Research Scholarship and went to New Zealand to carry out research on the magnetic properties of New Zealand volcanic rocks, for which he was awarded a Ph.D. by the University of London. Dr. Hatherton spent several seasons in Antarctica during 1955-64, and wintered over at Scott Base in 1957 as leader of the International Geophysical Year party. For this work he was awarded an O.B.E. and a Polar Medal for 1958. In 1959-60 Dr. Hatherton spent a year at the California Institute of Technology on a Commonwealth Civil Service (Harkness) fellowship. He is editor of a treatise on *Antarctica*, recently published in the United Kingdom, New Zealand, and the United States.

Promotions at Woods Hole Oceanographic Institution

IN recognition of scientific achievements of major importance over the past several years, the Woods Hole Oceanographic Institution has promoted seven members of its scientific staff to higher positions. Foremost among these was the appointment of Dr. Howard L. Sanders (zoologist) to the position of senior scientist, the highest rank of scientific appointment which is made by the Institution. Other appointments were to the position of associate scientist, and these included Dr. Carl O. Bowin (geologist), Dr. John E. Gordon (chemist), Dr. Robert R. Hessler (palaeozoologist), Dr. Richard M. Pratt (geologist), Dr. John M. Teal (biologist), and T. Ferris Webster (geophysicist). Dr. Sanders has been a member of the staff of the Woods Hole Institution since 1955 when he received his doctoral degree from Yale University. His special scientific interest lies in the area of marine benthic ecology, but he has also made extensive investigations of crustacean phylogeny. Of the other members of staff recently promoted, Dr. Bowin has made intensive studies of the density distribution of the Earth's crust and upper mantle. He has also done much to develop new techniques for the use of a digital computer on board a research vessel at sea. Dr. Gordon, on the other hand, has investigated electrolyte and non-electrolyte interactions in sea water, while Dr. Hessler has been concerned with studies on the evolution and morphology of Arthropoda and deep-sea animal communities. Dr. Pratt's special interest is in deep-sea topography. Dr. Teal has concerned himself with physiological ecology, and Dr. Webster with ocean current measurements.

Recruitment to the Civil Service

THE sixth report of the Estimates Committee for the session 1964-65, dealing with recruitment to the Civil Service, is discussed on p. 311, but the report is noteworthy for the memoranda submitted in evidence. Among

these, those submitted by the Civil Service Commission on the function and organization of the Civil Service Commission and that of the Treasury on recruitment to the Civil Service may be mentioned. Recruitment to the Civil Service is dealt with in memoranda by Prof. W. J. M. Mackenzie, by Mr. B. J. Holloway, by the staff side of the Civil Service National Whitley Council, and by the Acton Society Trust. The last-mentioned is supported by a further memorandum on the attitudes of civic university students towards an administrative career in the Civil Service. This is based on a survey of third-year undergraduate students at the University of Hull, undertaken following a suggestion made in the statement of evidence made to the Committee by the Acton Society Trust. A further memorandum on recruitment to the Civil Service is by the Warden of Nuffield College, Oxford, Mr. D. N. Chester. Another on the same subject by the Business Economists Group is also appended; the Institution of Professional Civil Servants has a memorandum on recruitment to the professional and technical classes; finally, one on the recruitment of girls to the Civil Service is submitted by Miss Margaret Miles.

Anglo-Romanian Agreement on Co-operation

A FORMAL agreement on co-operation has been concluded between the Royal Society and the Academy of the Socialist Republic of Romania with the signature in Bucharest by Academician D. Dumitrescu, First Secretary of the Romanian Academy, and in London by Sir Patrick Linstead, Foreign Secretary of the Royal Society. The agreement makes provision for; (1) the annual exchange of three scientists from each side for lectures and visits to specialized scientific institutions in the other country for periods of fourteen days; (2) the annual exchange of up to two scientific research workers from each side, for a nine-month period in each case, to study fundamental problems in some aspects of the physical and biological sciences, including their applied aspects. The agreement also calls for the exchange of periodical publications of the two sides and for the encouragement of further such exchanges of publications in specialized branches of the physical and biological sciences between the respective corresponding institutions in the United Kingdom and Romania.

Eleventh Pacific Science Congress

THE eleventh Pacific science congress of the Pacific Science Association will be held at the University of Tokyo, Japan, during August 22–September 10, 1966, under the auspices of the Science Council of Japan. The inaugural meeting will be held on August 22 and the general meeting on September 3. The first week of the congress will be devoted mainly to symposia, the second to divisional meetings and the third to scientific tours. The organizers are not limiting the number of scientists attending the congress. The branches of science covered by the Pacific Science Association include: meteorology; oceanography; geophysics; geology and soil science; biology; agriculture; forestry; animal science and conservation; fisheries; marine and freshwater sciences; nutrition; public health and medical science; social sciences; anthropology; geography; scientific information and museums. Symposia and divisional meetings will be held on specific topics in these fields. There will also be two congress symposia on (a) population problems in the Pacific, and (b) air and water pollution in the Pacific area, as well as four special symposia with exhibitions and demonstrations on vessels and instruments for oceanic and freshwater research, marine park, primate biology of the Pacific area and tsutsugamushi disease. It is hoped that various meetings of other international scientific organizations will be held in Japan concurrently with the congress.

The Royal Society, as the United Kingdom representative institution in the Pacific Science Association,

will be sending an official delegation of ten members to the congress. Members attending other meetings to be held concurrently with the Pacific science congress are invited to become members of the congress, and in addition any qualified scientist may attend the congress and participate in the two weeks of meetings without presenting a paper. Representative institutions have been requested to accredit all members of the congress: the Organizing Committee, and any United Kingdom scientist planning to attend is asked to inform the Executive Secretary, the Royal Society, Burlington House, London, W.1.

High-pressure Science and Technology

THE recent international conference on "High Pressures", held at Le Creusot, France, emphasized important common interests, particularly in engineering and experimental techniques, which link all high-pressure activities. At a special meeting, British delegates felt that better interchange of information between specialist activities would greatly accelerate progress in the United Kingdom. A committee was elected to: (1) organize meetings promoting contacts between specialists in different fields at which informal discussion would be encouraged; (2) provide a source of information on high-pressure activities in Britain, and liaison with American, Continental and other groups; (3) set up an association in which all interested in high pressures could join; (4) act as an advisory body to the Government and other authorities. The committee was chosen to represent a variety of interests and will be enlarged as necessary. Members are: K. E. Bett (Imperial College of Science and Technology); C. C. Bradley (National Physical Laboratory); C. H. L. Goodman (Standard Telecommunications Laboratories, Ltd, Harlow, *Acting Chairman*); W. R. Manning (St. Albans, Herts). All groups in Britain working with high pressures are urged to write to the committee giving a brief outline of their interests. This will enable a provisional directory of high-pressure research to be compiled which will be circulated to all who write in. It will also form the basis for the association, and for deciding the topics for the first research meetings. Letters should be sent preferably to the acting chairman, but any committee member would be pleased to answer queries.

Scientific Periodicals from the U.S.S.R.

THE 1966 catalogues of Russian newspapers and magazines procurable on a subscription basis through national agencies for Soviet books list several hundred scientific periodicals and more than 250 sections of the *Journal of Abstracts* and the *Engineering Index*, all of which are readily obtainable by Western readers if order are placed six weeks in advance of publication. An unwelcome feature of these 1966 lists is the rising cost of Russian journals of an academic or technical character, the price of which in most instances has advanced by 18–19 per cent since 1963. Annual charges for volume of the *Journal of Abstracts* (*Referativnyi Zhurnal*) series have gone up by some 30–40 per cent in the same period. In numerous instances these Russian scientific periodicals, characterized a decade ago by their relative cheapness, are now appreciably more expensive than their Western counterparts. It is significant that no comparable advances are scheduled in the price of newspapers and popular magazines and propaganda literature.

Soils of the Mendip District of Somerset

A RECENT memoir of the Soil Survey of Great Britain, by D. C. Findlay, gives an account of the soils and land-use of the region between Weston-super-Mare and Bridgwater and extending inland to Shepton Mallet (*The Soils of the Mendip District of Somerset*. Sheets 279 and 280. Pp. viii + 204 + 9 plates. Harpenden: Rothamsted Experimental Station, 1965. 35s.). The area surveyed extends to 279 square miles and includes the Mendip

and of limestone plateau at about 800 ft., surmounted four Old Red Sandstone hills, and the flat belt of alluvium, constituting the Levels, along the eastern side of the Severn Estuary. Exposed rocks range from the Devonian to the Jurassic systems, while the superficial deposits accumulated since the Pleistocene period include beds of estuarine and riverine alluvium interbedded with peat. Distance from the coast and increases in altitude account for wide variations in local climate and length of growing season. For example, the average rainfall is about 32 in. on the coast and 50 in. on the highest ground; sunshine and temperature display similar tendencies, while moisture-deficient periods may last during six months on the coast but only during June and July on the Mendips. There is a short discussion of the vegetation changes brought about by clearances of the oak-ash woodlands of the uplands, by agricultural improvements in the vales and by peat cutting on the moors. Six chapters are devoted to an explanation of soil formation and classification, and to details of the mapping units, including profile descriptions and analytical data. The soil conditions are then discussed in relation to land-use and types of farming, and there is a useful appendix dealing with the land-use limitations of the soil series. There is a list of references, a subject index, and two maps.

Tropical Timbers

FROM Belgium comes a very detailed account of the members of 67 tree species of the Congo (*Publications de l'Institut National pour l'Etude Agronomique du Congo. Mois du Mayumbe*. Par Joseph Fouarge et Georges Gerard. Pp. 579+57 planches. Bruxelles: Institut National pour l'Etude Agronomique du Congo, 1964). These are the principal timber species of Mayumbe, but not a few are to be found in the West African high forest and others are very closely related species. Each species is treated separately. The results of physical and mechanical tests are listed and notes are provided on the relative susceptibility of the timber to insect and fungal attacks. For many of the species a set of four microphotographs illustrates anatomical characteristics, and these are accompanied by detailed descriptions. A final section to the volume is intended for timber merchants and others interested in the uses of timbers, but a word of warning is added directing attention to variations which may occur in the same species. Statistics of the

physical and mechanical properties and the relative durability are tabulated and sections are given recommending timbers for particular purposes such as cabinet work, furniture, mouldings, carpentry, turnery, shingles, pulleys, sleepers, paving-blocks, piles, sluice-gates, marine constructional work, small boats, barrel-making, matches, pulping and other uses. This is a most useful reference work and the authors deserve praise for what they have accomplished.

Announcements

PROF. J. C. WHEATLEY, University of Illinois, has been awarded the fourth Simon Memorial Prize in recognition of his outstanding work on the properties of liquid helium-3 at very low temperatures. The Prize of £250 was established as a memorial to Sir Francis Simon and is awarded by the Committee of the Low Temperature Group every two or three years for outstanding contributions in the field of low-temperature physics.

THE second conference on "The Countryside in 1970" will be held in London during November 10-12. Further information can be obtained from the Royal Society of Arts, John Adam Street, London, W.C.2.

A SYMPOSIUM on "The Chemistry and Technology of Polyvinyl Chloride" will be held at the Bradford Institute of Technology during November 5-6. Further information can be obtained from the Registrar, Bradford Institute of Technology, Bradford 7.

A COLLOQUIUM on "Diet and Diabetes", arranged by the Scottish Group of the Nutrition Society, will be held at the Royal Infirmary, Edinburgh, on October 30. Further information can be obtained from Dr. C. F. Mills, Rowett Research Institute, Bucksburn, Aberdeen.

A SEMINAR on "Formulating International Science Policy", arranged by the Science of Science Foundation, will be held at the Foundation on November 15. Further information can be obtained from the Science of Science Foundation, c/o the Ciba Foundation, 41 Portland Place, London, W.1.

A MEETING on "Nuclear and Engineering Ceramics", arranged by the Basic Science Section of the British Ceramic Society, will be held at Harwell during October 25-27. Further information can be obtained from Dr. J. P. Roberts, Houldsworth School of Applied Science, the University, Leeds 2.

SECOND INTERNATIONAL CONFERENCE ON PROTOZOOLOGY

THE first International Conference on Protozoology was held in Prague in 1961, and the second at the Imperial College of Science and Technology in London during July 29–August 5, 1965. Approximately 570 delegates attended the Conference from 26 countries; 370 papers or films were read or shown.

In place of full proceedings, a shortened version of the papers was printed and given to delegates on arrival at the Conference, in a volume entitled *Progress in Protozoology*¹. This service was much appreciated and certainly is preferable to reports of congresses, which are not produced sometimes until as long as seven years after the meeting has ended, while the abolition of formal proceedings allows speakers a greater freedom to speculate and report on very recent work.

The patron of the Conference was H.R.H. the Duke of Edinburgh; the honorary president was Prof. E. Fauré-Fremiet, and the Conference was organized by a national committee under the chairmanship of Prof. P. C. C. Garnham.

The annual meeting of the Society of Protozoologists was held under the presidency of John Corliss (Chicago) during the course of the Conference.

The Conference was divided into two parts: the mornings were devoted to plenary sessions based on single topics; the afternoons to special symposia and contributed papers in four simultaneous sessions. At the end of the afternoons, ciné films were shown. The plenary sessions were selected to give non-specialized workers the present views on the following subjects: morphogenesis and life-cycles, types and preservation of strains, genetics, biochemistry and physiology, cytology and ultrastructure, and locomotion.

The afternoon sessions were devoted to specialized subjects, including: marine protozoa, piroplasms, protozoa of invertebrates, metabolism and drug action, cultivation of Protozoa, ecology of free-living Protozoa, ecology and host-parasite relationships, and little-known parasitic Protozoa. The remainder of the contributed papers were arranged around their individual subjects, such as *Toxoplasma*, malaria parasites, coccidia, and ciliates. The day after the close of the Conference itself, a symposium was held on the classification of the Protozoa, when various schemes, originating from the Society of Protozoologists, from the U.S.S.R. and from Poland, were discussed. No finality was reached, but arrangements have been made for the continuation of this discussion by the International Commission on Protozoology. This body was formally instituted at the Conference, following a proposal by Prof. Pierre de Puytorac (Clermont-Ferrand). It has the responsibility for organizing future International Conferences, to work for the establishment of relations with other international biological organizations, such as the International Union of Biological Sciences and Unesco, and particularly to appoint various committees to consider such subjects as the preservation of types, the maintenance of culture collections, the revision of systems of classification of the Protozoa, and the participation of protozoology in the International Biological Programme. The Conference itself passed a resolution requesting that the World Health Organization should be invited to convene a meeting for discussing how international co-operation could assist in the preservation of strains and types of Protozoa. The Conference also resolved that an abstracting service for protozoology is highly desirable, and the feasibility of the provision of this service is to be investigated. The final resolution of the Conference was that the third International Conference on Protozoology should be held in Leningrad in 1969.

The importance of the Protozoa in the whole field of genetics was emphasized by Sonneborn (Indiana), who pointed out that while work on viruses, bacteria, yeasts etc., appeared to have overshadowed that on Protozoa, it was nevertheless the protozoologist who, in the past, had pioneered a number of important routes for use in gene genetics. The Protozoa are likely to become increasingly important in this field, by virtue of their special suitability for investigating certain types of genetical activities including the special role they have in cytoplasmic genetics. This aspect was further developed by Preer (Philadelphia) in a discussion on *Kappa* and its relatives; showed that the mate-killing *mu* particle is maintained by the gene *M*, by producing "'metagons'"—particles which prevent destruction of *mu*. Metagons in extracts prevent loss of *mu* in metagon-depleted paramecia. The latter are produced by treating mate-killers with ribonuclease, replacing *M* genes by *m* genes using suitable crosses at autogamy. Metagons are present in the RNA extracts from ribosomes of paramecia bearing the *M* gene. Metagons hybridize well with DNA from paramecia containing *M* genes and poorly with DNA from paramecia containing *m* genes. Consequently metagons are thought to be messenger RNA. Metagons from paramecia, when introduced into certain ciliates such as *Didinium*, become self-reproducing, like RNA viruses². Recent Russian work, for example, by Judin (Leningrad), involving nuclear transplantation and amoebae, appears to minimize the control of genetic effect by the cytoplasm; he concludes that the inheritance of all the characters studied is conditioned exclusively by the nucleus. Grell (Tübingen) explained the new ideas on sexuality in foraminiferans, in particular autogamy or the mating of gamonts which could be differentiated into two morphologically similar types, reacting differently in the course of their lives.

There were numerous contributions from the French School (headed by Fauré-Fremiet, de Puytorac, Hovasse-Savoie, Mme Noirot-Timotheé and others) on the ultrastructure of the ciliates, and the structures were not merely described, but also considered from the point of view of their nature, morphogenesis, and mode of action.

The paper by Satir (Chicago) presented evidence for a sliding filament mechanism in the peripheral fibres of flagella and cilia. The 'doublets' consist of a longer and shorter filament; the shorter filaments are apparently different in the two cases and they are always distal to the cell of origin compared to the longer filaments. This agrees with expectations for sliding-filament models of filament function where the filaments at the bottom of the cross-section would move out past those at the top to accommodate curvature.

Progress has also been made in other aspects in the study of flagella and cilia. The great versatility of these organelles, especially in relation to the presence and arrangement of mastigonemes, was stressed by Jahn (Los Angeles). The mathematical analysis of the hydrodynamic principles involved in both flagella and cilia has advanced considerably, as illustrated by the papers of Rikmenspoel (New York), Holwill (Dorking) and Machin (Cambridge). Further, the co-ordination of ciliary action was shown by a number of speakers to be mediated mechanically and not, as has often been assumed, by the transmission of neuro-motor impulses by infra-ciliary fibres. The Polish workers in particular (Dryl, Grebecki and others) reported extensive experimental work correlating various forms of ciliary activity with surface potential, thereby providing a physiological interpretation of ciliate movement and reaction (for example, the induction of anodal galvanotaxis).

as in *Paramecium caudatum* by membrane calcium). Nelson and Warmouth (Boston) made an attempt to demonstrate learning in *Paramecium caudatum*, in which paired mechanical stimuli, paired with light or absence of light, were presented to individual animals in a designated region of a capillary test chamber. The animals avoided the area in which the mechanical stimuli were applied only under conditions of low-intensity illumination. Although avoidance persisted for a period of several minutes following cessation of mechanical stimuli, this response cannot be interpreted as learning since it was not dependent on pairing of any other stimulus with the mechanical stimulus. Further, during stimulation of one animal, a second animal also present in the chamber, but not receiving the stimuli, developed the avoidance response to the area in which the first animal was stimulated. Since it is unlikely that mechanical stimulation produces changes directly in the medium, it is suggested that a material is elaborated by paramecia in response to noxious stimulation. A simpler aspect of locomotion was beautifully demonstrated by Freyvogel (Basle) in a speeded up 16-film to show the movements of malarial ookinetes. In recent years their inherent motility had been denied. The film clearly demonstrated that two types of movement are to be distinguished: in the first the ookinete is attached to the substrate with one pole as a sucker; in the second the free part of the body it carries out circling movements, but it remains on the spot. By the second a more or less even locomotion is made possible; this is brought about by circular contraction waves which originate at the anterior pole and which migrate on the surface of the body, all over its central portion. With reference to the substrate these contraction waves remain on the spot and the ectoplasm with its inclusions is driven forward through them. In this way, on one occasion, an ookinete was shown to cover about 100 μ within 40 min.

Few papers dealt with amoeboid movement, doubtless because this has been the subject of a recent symposium somewhere, but the demonstration by Seravin (Leningrad) that amoeboid locomotion is produced not by a single but by many physiological mechanisms strikes a new note.

While the importance of the organelles, as revealed by electron microscopy, is fully recognized, Cheissin (Leningrad) pointed out that their presence or absence should not be regarded as an indication of the taxonomic position of the organism concerned; such organelles have a common function throughout the animal and plant kingdoms, and their existence is an indication of function rather than of taxonomy. On the other hand, as Jahn (Los Angeles) states, locomotion itself has always been regarded as the most important and generally accepted single taxonomic criterion of non-fossil Protozoa from subphyla to species, and this function of the organism is dependent on such organelles. Polyansky (Leningrad) extended these ideas in an interesting discussion on evolution in the Metazoa and Protozoa; in the former, there is a tendency to a decrease in the number of organs, in the latter an increase (polymerization). This is accomplished either by increasing their actual number (for example, the nuclei of opalinids), their duplication as in *Giardia* or their differentiation into two types as in the macro- and micro-nuclei of ciliates. A further extension of the process is by polyploidization with the emergence of new evolutionary forms.

The foregoing topics largely concerned the free-living Protozoa, although many of the conclusions can also be applied to the parasitic forms. The latter represent specialized subjects, progress on which has advanced since the preceding conference on predictable lines.

The subject of piroplasms was selected as representing an area where important gaps in knowledge exist, in the hope of stimulating fresh work, but unfortunately little major progress in relation to the life-history of these organisms or even on their taxonomic position has yet been effected.

It was obvious that a great deal of work is being done on the biochemistry of the Trypanosomatidae, and this is commencing to throw light on their phylogeny and classification. Guttman (New York) explained the different nutritional requirements in special media of *Leishmania*, *Leptomonas* and *Crithidia*.

Artificial immunization of animals against the malaria parasite (Margaret Weiss, Michigan) and the trypanosomes (Soltys, Cambridge) has at last been accomplished. In the former case, mice were actively immunized by the injection of a strain of *Plasmodium berghei* which had become non-invasive for mice. This strain had lost its infectivity for mice, though not for rats, following a number of sojourns in tissue culture in a medium containing hamster serum. An initial immunizing dose containing few parasites was followed 2 weeks later by a booster injection containing 1-2 million parasites of the same strain. The mice were afterwards challenged by the parent strain which kills control mice within 3 weeks. Immunity was slow to develop, and during an initial period extending for about 4 weeks after the booster injection the mice were particularly susceptible, and succumbed even faster than the controls to challenge infection with the virulent strain. But after this sensitive period good immunity developed which was solid in many cases; in others single parasites were seen, and in a few cases peak parasitaemias of 1-2 per cent red blood cells parasitized were observed. This degree of immunity persisted for about 4 months. Soltys showed that *Trypanosoma brucei*, inactivated by treatment with β -propiolactone, could be used as a living vaccine to protect mice against the homologous, virulent strain.

The recent discovery by Mme Landau (Paris) of a new species of rodent malaria parasite is likely greatly to facilitate malaria research, because *Plasmodium chabaudi* represents a model where an infection in a small laboratory mammal can be used with much greater ease and success than the well-known *P. berghei* in mice or *P. cynomolgi* or *P. knowlesi* in monkeys. The latter systems present many technical difficulties; on the contrary, the new species is easily transmitted by mosquitoes and enormous numbers of exoerythrocytic forms are produced. This work stems from the highly successful recent experiments of Yoeli² (New York) on the transmission of *P. berghei* and the discovery of its exoerythrocytic cycle in the liver of mice and hamsters.

Further knowledge of the ultrastructure of the Sporozoa was advanced by Scholtyssek's (Bonn) work on sporozoites of *Eimeria perforans*, Cheissin's (Leningrad) on *E. bovis*, Sheffield and Hammond's (Utah) also on *E. bovis*, Vivier's (Lille) on gregarines and coccidia, and Bardele's (Tübingen) on *Eucoccidium dinophili*.

A special topic of the first Conference was *Toxoplasma*; little new information has emerged in the past four years relating to the life-history of this organism until very recently when Hutchinson (Glasgow)³ described the apparent transmission of *Toxoplasma* through the egg of *Toxocara cati*. He did not give a paper on this subject, but discussed the implications in the session dealing with the organism.

A newly discovered disease of man, due to the free-living amoeba, *Hartmannella castellani*, was described by Culbertson (Indiana), who gave details of his experimental work with this organism in rabbits and mice, and showed slides of the organism as found in the tissues from 7 fatal human cases.

The role of *Pneumocystis carinii* as a pathogen of man becomes more formally established following papers by Kučera (Prague), Frerking (Kansas) and Yaeger (New Orleans).

TYPOGRAPHY OF BACTERIA

AT an informal meeting of editors of journals in which bacteriological papers appear, and some other interested persons, it was agreed that a greater uniformity in typography was desirable; the following proposals, which arose from the meeting and from subsequent discussion, may be of wider interest.

It must be made clear that these proposals are concerned solely with typography and not with the more controversial subjects of classification or nomenclature.

(1) Nomenclature. The International Code should be followed. (*International Code of Nomenclature of Bacteria and Viruses: Bacteriological Code*: Ames, Iowa, Iowa State University Press, 1959.)

(2) Major ranks, such as the names of orders, tribes or families, are written in roman with an initial capital; for example, Enterobacteriaceae

(3) Binomials consisting of genus and species together are italicized, only the genus having a capital letter; for example, *Staphylococcus aureus*. [Note: A binomial which is considered invalid may be enclosed in quotes; for example, 'Bacillus typhosus'.]

(4) Sub-species (varieties) are italicized, without a capital, and preceded by 'subsp.' (or 'var.') in roman; for example, *Corynebacterium diphtheriae* subsp. *mitis*.

(5) Strains are printed in roman and are capitalized only when derived from proper names; they are preceded by 'strain' in roman or may be regarded as part of a trivial name (see 9); for example, *Staphylococcus aureus* strain Oxford, the Oxford staphylococcus.

(6) Groups and types are printed in roman and designated by capital letters and arabic figures respectively; for example, *Streptococcus pyogenes* group A type 1.

(7) Generic names are italicized either when used alone to mean the whole genus as a genus or followed by 'sp.' or 'spp.' to indicate a culture which has been identified only as far as the genus. Otherwise when used either as nouns or adjectives they are regarded as trivials and printed in roman; for example, the genus *Brucella* . . ., culture yielded *Bacillus* sp., some escherichias may have salmonella antigens.

(8) Specific epithets are occasionally used alone, and are usually regarded as trivials and printed in roman; for example, the strains were of the abortus type.

(9) Trivial names should be in roman type and capitalized only when derived from proper names. (Not when names of diseases are used.) Generic names may be used trivially; for example, meningococcus, Koch-Weeks bacillus, haemophilus, spirochaete, typhoid bacillus.

(10) Anglicized plurals may be used for trivial names to avoid classically derived forms which may appear pedantic or clumsy; for example, salmonellas, mycoplasmas, actinomycetes, pseudomonads, leptospores.

(11) Hyphens should be used sparingly and never in italicized binomial (or trinomial) forms. A single word must be used to avoid confusion; for example, *Salmonella choleraesuis*, *Bacillus pseudotuberculosis* rodentium; but note: *Salmonella paratyphi* B.

(12) Abbreviations should be used with caution. Generic names may be abbreviated to a single capital letter except in titles; in summaries; when first mentioned in the text and when any possibility of confusion could exist; for example, *S. aureus* (see Cowan, S. T., *Science*, 120, 1103; 1954); specific epithets should never be abbreviated, except possibly in tables.

(Note: Special *ad hoc* abbreviations may sometimes be acceptable in text-books or abstract journals, so long as they are clearly explained in the text.)

(13) Salmonellas present a special problem as their nomenclature is still in dispute. It is not the purpose of this communication to discuss the merits of the various proposals but to suggest appropriate typography. The

following examples illustrate some of the ways in which same culture may be described. (a) A separate species, so written as a binomial in italics with the specific epithet in latinized form and in lower case; for example, *Salmonella londonensis* (this example is after Haupt, cited in *Bergey's Manual*, sixth ed. The latinized form of the word 'London' should, in fact, be 'londiniensis'). (b) As above but with the specific epithet unlatinized; for example, *Salmonella london*. (c) A variety of a large inclusive species and so written with the epithet in lower case italics; for example, *Salmonella kauffmanni* var. *londonensis*. (d) Serotype of a large inclusive species and written in roman with an initial capital if derived from a proper name; for example, *Salmonella kauffmanni* [serotype] London. (e) A trivially named serotype written in roman throughout with an initial capital if indicated; for example, *Salmonella* London.

(14) Notes: (i) Specific epithets should be a single word in lower case, but serotypes, being trivials, may have more than one word and capitals where required. See pars. 10 and 11; for example, *Salmonella saintpaul*, c.f. *Salmonella* Saint Paul. (ii) A hybrid or bastard composed of an italicized generic name and a roman serotype cannot be defended and should not be used; for example, *Salmonella* London.

(15) The nomenclature of salmonellas is discussed more fully by Cowan, S. T. (*Bull. Hyg.*, 32, 101; 1957). Here we would merely suggest that wherever possible a single usage should be adopted for use in a single communication.

A Note on the Typography of Other Micro-organisms

(16) Fungi and protozoa. Nomenclature is governed by the international botanical and zoological codes. In general, our suggestions for bacterial typography could apply.

(17) Viruses. The nomenclature of viruses is at present being considered by the Provisional Virus Nomenclature Committee of the International Association of Microbiological Societies. Until their findings have been accepted and approved we consider that names of viruses should be regarded as trivials. The following tentative suggestions for their typography may be helpful: (a) Viruses named after a disease should be written as separate words in lower case roman, except where the name of the disease is derived from a proper name; for example, measles virus, poliomyelitis virus, varicella zoster virus, herpes simplex virus, Newcastle disease virus. (b) Viruses named after a place or person should be written as separate words with an initial capital; for example, Cocksackie virus. (c) Classical or euphonious synthetic prefixes should be combined with the suffix 'virus' and written as a single word in lower case; for example, adenovirus, cytomegalovirus, echovirus, picornavirus, poliovirus. (d) Unpronounceable synthetic prefixes should be written as a separate 'word' entirely in capitals; for example, LCM virus.

Among those who make these recommendations are Sir Christopher Andrewes, formerly deputy director, National Institute for Medical Research; Dr. H. J. O'D. Burke-Gaffney, editor, *Bulletin of Hygiene*; Dr. S. T. Cowan, director, Central Public Health Laboratory formerly curator, National Collection of Type Cultures; Dr. R. M. Fry, editor, *Journal of Hygiene*; Dr. J. C. Kelsey, editor, *Monthly Bulletin of the Ministry of Health and Public Health Laboratory Service: Section II*; Prof. C. L. Oakley, editor, *Journal of Pathology and Bacteriology*; Mr. A. F. B. Standfast, editor, *Journal of General Microbiology*; Mr. G. Sykes, editor, *Journal of Applied Bacteriology*.

ANGLO-AFRICAN JOINT RESEARCH SCHEMES AND RECRUITMENT

A CONFERENCE was held under the auspices of the Centre of African Studies, University of Edinburgh, in association with the Ministry of Overseas Development, at the "Joint Research Schemes and Recruitment", at the University of Edinburgh during September 13-17.

Ninety delegates from universities, training colleges and colleges of advanced technology in Scotland, the North of England and Northern Ireland and Africa attended the conference. Representatives came from thirteen British institutions of higher education and fourteen African, together with representatives of the British Ministry of Overseas Development, the Commonwealth Association of Architects, the Architectural Association, the British Council and the Inter-University Council for Higher Education Overseas.

Although this conference was called originally to discuss joint research schemes between institutions of higher education in Scotland, the North of England and Northern Ireland and African universities and also recruitment in his northern region of Great Britain for African universities, it soon extended its terms of reference to include almost the whole field of relations between British and African higher educational institutions. This tendency undoubtedly grew from the fact that both the British and African universities find themselves in an exciting period of parallel development in a rapidly changing world.

In the past it has been common to consider that the relations between British and African universities were heavily weighted on the side of British initiatives. It soon emerged from the conference, particularly as a result of the contributions of the African delegates, that this was a two-way traffic and that the British universities would also benefit from an extension of their relations at all levels with African universities.

The conference, in its conclusions, stressed the necessity of improving, in all their ramifications, the channels of communication between British and African universities. Not only was it necessary to improve the existing channels of communication between the Ministry of Overseas Development, the Inter-University Council for Higher Education Overseas, and British and African higher educational institutions and to improve the information services on African educational possibilities in Great Britain of British professional organizations, but it was also important to set up regional committees of British universities to improve their own communications with African universities. In particular, there should be a committee of the Scottish, North of England and Northern Ireland universities, training colleges and colleges of advanced technology for this purpose.

A major decision of the conference—one in which it struck out in a new direction in British-African higher educational relationships—was that throughout the British Isles a number of committees based on the major academic disciplines and organized on trans-university lines should be set up to initiate new joint research schemes and activities between British and African academic institutions and to review existing joint activities periodically.

The conference urged that a directory of research in progress in African universities should be produced as soon as possible. Furthermore, it urged that a directory of specific post-graduate opportunities in British universities (their individual research interests and achievements; the facilities which they offered for research; the size of their post-graduate departments; and their reputations in their respective fields) aimed at the particular needs of African post-graduate students should be compiled as soon as possible. This, it was suggested, should be revised frequently, in order to present the

potential African postgraduate student with as up-to-date a picture as possible of postgraduate prospects in a rapidly changing scene.

The conference stressed strongly the importance of both official and unofficial funds being made available, not only in improving the conditions of secondment of British academic workers in African universities but also for improving the position of the permanent staff, many of whom were from Great Britain, in African institutions of higher education. The financial implications of secondment from British to African universities should give greater attention to ensuring that seconded personnel do not lose financially, as is so often the case, during their period of secondment to an African university. Careful safeguards to this effect should be written into their agreement with an African university. Greater efforts should be made at the British end to supply African universities with technicians and 'middle level' administrators and secretaries.

Secondment of senior personnel (such as deans of faculties and heads of departments) from British to African universities, it was considered, should be for periods sufficiently long to ensure that programmes which such individuals initiated in African universities were properly launched.

The conference directed special attention to the problems of African post-graduate research students and stressed that greater attention should be given to placing them in those British universities in which their interests and talents could be most effectively developed. Departments in British universities should be discouraged from assuming responsibility for African postgraduate students for whom they could not provide viable research topics, adequate supervision and the necessary materials for research.

In its detailed consideration of joint research schemes between British and African higher educational institutions—many of which were developed in detail in a series of inter-disciplinary discussion groups—the conference stressed that British universities should endeavour to participate in existing joint research schemes with African universities and in schemes which have been initiated in African universities themselves. While recognizing, however, that such approaches are less wasteful in time, money and manpower than joint research schemes launched independently in Great Britain, it was considered important not to discourage independent schemes in those fields where British institutions of higher education were in a position to give a lead to African universities.

The conference urged that experiments should be made by the universities of Scotland, the North of England and Northern Ireland in setting up international halls of residence and British-African halls of residence in order to go some way towards ameliorating the growing crisis in student accommodation in British universities.

The extent of the conference's detailed deliberations will be reported in the *Proceedings* which it is hoped to publish shortly. In anticipation of these, it should be indicated that those deliberations ranged into unexpectedly detailed fields. For example, there was a lively discussion on the necessity of continuing the external examiner system in African universities. Again, it was suggested by a considerable number of individuals at the conference that there were certain fields such as African history in which external examiners could be used from African universities in British universities.

Finally, the conference expressed a strong wish that the many recommendations for improving relations between British and African universities which had been made in its various sessions should be translated into action as

soon as possible at all levels, both institutionally and individually. The conference saw in the suggestion indicated here that academic disciplinary committees should be established for this purpose, one of the most hopeful signs

for the future. It was considered that in their meetings the future such academic disciplinary committees should consider the possibility of holding further conferences the kind held in Edinburgh.

MODERN TECHNIQUE IN RESTORATION OF ROMAN MOSAICS

THERE is an inborn fascination to many of us, besides archaeologists and historians, in the discovery and unearthing of relics of life as it existed centuries ago. None of these is perhaps more generally exciting and popular than the Roman mosaic pavements, those skilfully constructed floorings in regular cubes of stone of many colours, beautifully contrived in patterns and pictures, frequently found in western Europe, far less common in Britain. Proof of life as it existed in Yorkshire during A.D. 100–400, as evidenced by the discovery of two excellent examples of Roman mosaic handiwork, is furnished by the Rudstone pavement, a few miles inland from Bridlington (1933), and by one at Brantingham, near the north bank of the Humber, a few miles west of Hull, unearthed in 1962. Some faithfully illustrated records of these two mosaics and particularly the manner of their preservation are contained in a recent publication entitled *Araldite in the Restoration of Roman Mosaics**.

At Rudstone three mosaics were originally uncovered and housed on site for many years. However, they began to deteriorate and were ultimately removed to Hull Museums for permanent preservation, this work being undertaken by the Museum staff and successfully completed in 1962. "One mosaic, 12½ ft. × 10½ ft., has a figure of Venus as its centrepiece; another, 11 ft. by 11 ft., shows a geometric pattern, while the third, depicting marine life, measures 10 ft. × 5 ft. These panels are now beautifully displayed in the museum." Their removal from site was, however, a matter of great concern and cost. The geometric panel, for instance, with its steel reinforcement, weighed 4½ tons; its display on a wall entailed the use of temporary scaffolding for its erection, a costly and laborious job. The lessons had been learnt with these Rudstone mosaics the hard way; when it came to the question of lifting the newly discovered Brantingham pavement, different methods of preservation were resorted to, involving the use of an 'Araldite' (CIBA) epoxy resin formulation and a novel technique.

The Brantingham pavement apparently formed the floor of the largest room in what is thought to have been a distinguished Romano-British villa. It originally measured 36 ft. × 26 ft. It is the largest example of Roman mosaic work so far discovered in Yorkshire. Unfortunately part of this mosaic had suffered damage by

collapse into flues of an underlying hypocaust, but number of large panels were well preserved, remove and are now in course of preparation for exhibition in Hull Museums. Some smaller sections of the mosaic were taken away flat, but other larger portions were transported by what is known as the 'rolling-up' technique. Briefly, the procedure is as follows: to ensure absence of moisture a metal scaffold frame is erected over the pavement and on this a plastic sheet is stretched; butane gas heaters are then directed on to the pavement for some three days or so; at the end of this drying, two coats of a polyvinyl chloride solution are spread over the mosaic, a bandage material laid thereon, and a top sealing coat of polyvinyl chloride. The next operation—a difficult one—is the actual rolling up of the pavement; according to this account: "This was done on a cardboard roller, 2 ft. in diameter, strengthened internally and filled with a suitable axle. The tesserae (the individual stone cubes forming the pavement) were cut away from the mortar with long iron blades and several workers helped to turn the roller and ensure that the pavement was evenly wound. As they went on to the roller, the layers were interleaved with two sheets of corrugated paper and a strong dust sheet which was pulled tightly over the tesserae to keep them in place". Thus the sections of the pavement are transported to the museum.

The unrolling stage is the next operation and it is here that the 'Araldite' resin plays its part. The major sections of the pavement are unrolled face down on a sloping surface; the edges are boxed in with timber to make a container for the backing; any loose mortar is cleaned off; then an 'Araldite' coat is applied together with chopped glass fibre. Finally, this is backed up with 2 in. of vermiculite and iron reinforcing bars bonded with an 'Araldite' resin formulation. The whole process results in a light but rigid structure. Compared with the Rudstone mosaic panels, it is estimated that this technique results in the weight of the Brantingham panels being less than a quarter per unit area.

The great advantages of these cured 'Araldite' epoxy resins for this sort of work are their stability, resistance to chemical attack and moisture. Furthermore, they possess strong adherent properties to a host of different materials, such as stone, glass fibre and vermiculite. It is indeed no boastful claim that "... these beautiful pavements are now permanently preserved for the benefit of posterity ..."

* Ciba (A.R.L.), Ltd., *Technical Notes* (July, 1965): *Araldite in the Restoration of Roman Mosaics*. Pp. 12. (Duxford: Ciba (A.R.L.), Ltd., 1965.)

A PROPOSAL ON NATURE'S TIME-SCALE

By PROF. NEIL G. McCORMICK

Department of Microbiology, School of Medicine, University of Virginia, Charlottesville

IT has become increasingly obvious through the various cosmological and relativity theories that we live in a non-linear universe. As has been aptly pointed out¹, there is a tendency to make simplifying assumptions about all observable phenomena in order to explain them in a linear manner. In a way this has lulled us into the belief that most processes may be considered to exist in some theoretically idealized state. Hence, many observations of non-linear processes are compromised by considering "... equations to be linear for a sufficiently small displacement

..." or, "... in a certain range the curve can be approximated by straight lines as shown". However, these idealized assumptions (that is, homogeneity, frictionlessness, weightlessness, temperature of absolute zero, perfect gas, perfect vacuum, etc.) are never observed in reality, and in all likelihood never occur in Nature. Even though such assumptions may aid greatly in understanding the mechanisms involved, they do not lead to a complete description of the process. As stated by D. W. Thompson² in a discussion concerning the regeneration of tadpole

s: "... it is obvious that the value which we have used for the latter portion of the curve (however closely it conformed to) is only an empirical value; it has only a temporary usefulness, and must in time give place to a formula which shall represent the entire phenomenon, from start to finish".

This communication proposes a non-linear function of time which appears to describe the time-course relationships of a variety of processes.

Several proposals have been made recently on re-evaluating some of the basic units of measurement. Aldwin and Tonks⁶ propose the adoption of a logarithmic pressure scale which would encompass both extreme vacuums and high pressures with equal facility. The authors emphasize the advantages of converting to a logarithmic scale and refer to the established precedence for such a scale in the pH system. This scale would permit the recording of vacuums approaching that of an absolute vacuum, a limit (it should be emphasized) which has never been attained experimentally. Likewise, a proposal for the re-orientation of the temperature scale has been advanced by Georgian⁴ in which he maintains that new units are necessary to describe the proper dimensions for temperature, that is, specific energy. When the proper conversion is made, the gas constant, R , becomes unity and the Boltzmann constant, k , is recognized as the reciprocal of the vagadro number. In addition to the resulting simplification it may be appropriate to consider the temperature scale as logarithmic also. As in the case of an absolute vacuum, a temperature of absolute zero is a limit which may be closely approached but never attained. The adoption of logarithmic scales would provide a continuous connecting link between the infinitesimally small and the infinitely large.

Proposals which consider the nature of macrocosmic time as exponential or logarithmic functions have been advocated by Milne and by others⁵⁻⁷. A logarithmic nature to psychological perceptions of time has also been noted^{8,9}. If time is truly non-linear then this non-linear function should be equally applicable to processes describing microcosmic events. In whatever process the time parameter is involved there should exist some descriptive function which incorporates a non-linear function of time.

An investigation of the kinetics of germination of bacterial spores has led to the derivation of an empirical equation which accurately describes the sigmoidal time-course curves obtained¹⁰⁻¹². The equation, $Y = \exp(-kt^{-c})$, may be converted into a linear function by plotting $\log \log 1/Y$ versus $\log t$, where Y is the fraction of the process completed in time t , k is a function of the intercept at $\log t = 0$, and $-c$ is the slope.

The equation also successfully describes the sigmoidal time-course curves obtained from a variety of different processes. Further applications suggest that time-course curves which appear to be hyperbolic rather than sigmoidal are also described by the equation. Representative types of time-course curves from a variety of processes are shown in Fig. 1. The time-scale is expressed in arbitrary units depending on the nature of the specific process being measured. Curve A is representative of processes which appear to reach completion very rapidly, such as fast chemical reactions and, if inverted, even survival curves. Curves B and D represent processes describing rectangular hyperbolas passing through the origin, such as observed with many enzymatic and chemical reactions. Curves C and E represent processes which describe sigmoidal time-course curves such as growth, certain chemical reactions, spore germination, enzyme induction, and a whole host of other naturally occurring phenomena. Curve F represents the type of process which appears to be linear with time, such as one which completes only a very small fraction of the total process during the period of observation. The curves shown in Fig. 1 were all generated by use of the equation by assigning to the constants, c and k , the values given in Table 1.

Table 1 THE VALUES OF THE CONSTANTS USED IN THE EQUATION $Y = \exp(-kt^{-c})$ TO GENERATE THE CURVES IN FIG. 1

Process	c	k
A	3.725	0.000286
B	0.6502	0.3558
C	1.536	3.224
D	0.4307	1.709
E	1.096	6.909
F	0.3010	4.606

Because of the variety of processes which have been examined and found to conform to the equation, the following premise is suggested: the time-course curves of all natural processes are sigmoidal whether or not an induction period or inflexion point can be detected during a particular observation. Examination in the classical sense of curves A , B and D in Fig. 1 suggests that a tangent to the curve at the origin might be constructed and that the slope of such a line would give the maximum rate of the process. These suppositions have been extensively utilized in the formulation and development of classical kinetic theory. The same argument holds for curve F in which it appears that a straight line passing through the origin may be drawn through the points. If the foregoing premise is true, however, then all the curves actually must possess an inflexion point at a time other than zero although it may approach zero to any degree desired. Since each of the curves depicted was generated by the equation $Y = \exp(-kt^{-c})$, the inflexion points may be estimated mathematically¹³. Inspection of curves A , B and C suggests that they tend toward a limit of 1.0. However, this limiting value is not as apparent with the remaining curves. Curve F may appear either to increase indefinitely (if considered a straight line) or to approach a limit significantly less than a value of 1.0 (if curvature is acknowledged); however, the equation used to generate each curve is based on a limiting value of 1.0 as time approaches infinity. Curves D and E also appear to approach limits somewhat less than the maximum of 1.0 even when the usual methods of extrapolation to infinity are employed. It can be estimated by means of the foregoing equation that process F would require 2.82×10^6 units of time to reach 90 per cent of completion, process D would require 750 units of time, and process E , 64 units of time. Thus, the equilibrium value of a process determined by application of the foregoing equation may be appreciably greater than the value estimated by extrapolation procedures at present available.

Investigation of the possible physical significance and properties of the equation has led to the formulation of the

Fig. 1. Time-course curves typical of various types of processes generated by the equation $Y = \exp(-kt^{-c})$. The corresponding values for the constants are given in Table 1.

Fig. 2. Exponential relationships of the times required for processes A, B, D, E, and F to attain various fractions of completion versus the time required for the reference process (C) to achieve the same fraction of completion

following hypothesis: all naturally occurring phenomena proceed according to exponential functions of time and each process in Nature conforms to its own unique time scale. The refutability of the hypothesis may be examined by testing a corollary to the hypothesis; namely, that a process need not necessarily be timed by a clock, but may

be 'clocked' by reference to any other reaction in Nature. That is, the time required for any specific process in Nature to attain a certain degree of completion (or fraction of a limiting value) is exponentially proportional to the time required for any other natural process to attain the same fraction of completion. This is illustrated in Fig. 2. The times required for the process represented by curve (the reference 'clock' in this case) to attain various fractions of completion (superimposed scale) are plotted along the abscissa while the times required for each of the other processes to reach the respective fractions of completion are plotted along the ordinate. If a complete and accurate record of the reference process is known, and if the extent of completion of the second process is known at two different times then the course of that process may be predicted for any time. The dashed line represents a guideline of the reference curve C plotted on both the ordinate and abscissa.

The final proof of the hypothesis lies in testing the foregoing corollary with accurate data from a wide variety of different processes. In order to calculate the fraction of completion at any time and to apply the experimental data, it is imperative that the exact zero time be known as well as the true limiting (or equilibrium) value of the process as time approaches infinity.

SUBCUTANEOUS SARCOMATA IN HAMSTERS INDUCED BY ROUS SARCOMA VIRUS (BRYAN)

By PROF. M. L. EIDINOFF, B. BATES, M. STEINGLASS and PROF. J. R. HADDAD

Divisions of Biophysics and Microbiology, Sloan-Kettering Institute for Cancer Research, New York

WHEN the investigation reported here was begun (June, 1964) the Bryan strain of the Rous sarcoma virus (RSV) had been found to be oncogenic for fowl only, while several strains of RSV, including the Carr-Zilber and Schmidt-Ruppin, produced tumours in a variety of

mammalian species¹⁻³. The experiments of Stewart and Landon (reported by S. E. Stewart at the Stern symposium, "Perspectives in Virology", February 1964) suggested that RSV (Bryan) could be 'activated' to be oncogenic for mammals by suitable treatment with a hamster embryo

Table 1. INCIDENCE OF TUMOURS FOLLOWING INOCULATION OF ROUS SARCOMA VIRUS IN NEW-BORN HAMSTERS

Group	Inoculum	Pock-forming units	Animals	Incidence of tumours (days)						Died	+	-	% +
				0-14	15-20	21-30	31-60	61-90	91-200†				
A	RSV (Bryan)*	2×10^4	21	0	0	1	0	0	1	1	2	18	10
B	RSV (Bryan)† reconstituted	1×10^5	122	0	1	12	4	2	7	25	26	71	27

§ Schmidt-Ruppin strain, Lots 11 and 29, University Laboratory, Highland Park, New Jersey. Samples diluted with Eagle's basal medium plus 5 per cent calf serum.

¶ The experiments were terminated at 200 days.

tract⁴. These findings led to an investigation in our laboratory in which RSV (Bryan) was inoculated into v-born hamsters under several experimental conditions including treatment with hamster embryo extract. We have found that RSV (Bryan) can yield sarcomata in hamsters following inoculation (10^4 – 10^5 pock-forming units in 0.1 ml.) in new-born hamsters in the absence of any extract from rapidly growing tissue. Since these experiments were started, Rabotti *et al.* have reported the formation of gliomas and choroid plexus papillomata induced by intracerebral inoculation of RSV (Bryan) in w-born hamsters⁵.

RSV (Bryan, lots CT 951, CT 955 and CT 957) was provided by Dr. W. Ray Bryan, National Cancer Institute, a partially purified, pelletized preparation stored in 0.5 M sodium citrate. RSV (Schmidt-Ruppin, lots 11 and 29) was supplied by University Laboratories, Highland Park, New Jersey. Viral suspensions and control materials (0.1 ml.) were inoculated subcutaneously (at the nape of the neck) into golden Syrian hamsters (Manor Farms, New York) 24–48 h after birth. Virus preparations were assayed in pock-forming units by enumeration of pocks on the chorioallantoic membrane of chick embryos using standard procedures⁶.

In order to prepare RSV (Bryan), 'reconstituted' (Table 1, Group B), a pellet was prepared by centrifugation at 40,000g for 1 h followed by resuspension in Eagle's basal medium plus 5 per cent calf serum to the original volume. To prepare hamster embryo extract containing RSV (Bryan), embryos taken one day before parturition were minced and an equivalent volume of virus suspension was added. This mixture with an equal volume of 0.153 M potassium citrate (with 1.5 mg per cent hyaluronidase) was homogenized ('Virtis 45') at 4° for five 1-min runs at a setting of 10 with a 20-sec rest between runs. Eight volumes of 0.153 M potassium citrate were then added. The mixture was allowed to stand at room temperature for 30 min and afterwards kept at 4° for 24 h. The mixture was sedimented (International centrifuge) for 20 min at 4° and 1,500 r.p.m. and the supernatant was removed and spun again as above. The supernatant was cleared at 8,000g for 1 min (Servall centrifuge). The virus was then pelletized at 40,000g for 1 h (Spinco L) at 4°. The pellet was resuspended in a volume of Eagle's basal medium plus 5 per cent calf serum equal to the original volume of virus suspension. The preparation of hamster embryo extract (without addition of virus) was similar to that already described here and used as a control inoculum (Table 1, Group F).

The combined results of several experiments using RSV (Bryan), 10^5 pock-forming units, are shown in Table 1, Group B. Since the presence of 0.05 M sodium citrate in the RSV (Bryan) was observed to be toxic to the new-born hamsters, the virus suspension was 'reconstituted' at full titre in Eagle's basal medium plus 5 per cent calf serum. Progressively growing sarcomata had been observed in 26 of the 122 animals when the experiments were terminated after 200 days. Approximately half the animals receiving 1×10^5 pock-forming units of RSV (Bryan) plus hamster embryo extract developed tumours (Group C). Using a dose of only 2×10^4 pock-forming units of RSV (Bryan), about 10 per cent of the animals developed tumours (Group A).

Of the 148 control animals either inoculated with hamster embryo extract or Eagle's basal medium or not inoculated at all, no tumours were found after 200 days (Groups F, G and H).

Several experiments using the Schmidt-Ruppin strain are also summarized (Groups D, E). Based on the pock-forming units of RSV administered, the Schmidt-Ruppin strain was more oncogenic for the new-born hamsters used in this investigation than was the Bryan strain.

The results for Group B and C (Table 1) suggest a slightly enhanced oncogenic activity for the RSV (Bryan) exposed to the treatment with hamster embryo extract

described here. After we had observed substantial oncogenic activity in hamsters using the RSV (Bryan) samples available in our laboratory, we abandoned any further search in our system for the identity of the 'activating factor' suggested by the work of Stewart and Landon⁴.

The tumours were histologically sarcomatous (Fig. 1A), poorly differentiated and similar to those described by

Fig. 1. Sections of tumours in hamsters inoculated at birth with Bryan strain of Rous sarcoma virus (haematoxylin-eosin stain, $\times 128$). A, Poorly differentiated sarcoma. Pleomorphism; multiple nuclei; mitotic figure (lower left). Bryan CT 957; 2×10^4 pock-forming units diluted in Eagle's basal medium plus 5 per cent calf serum. Tumour onset: 24 days; excised after 10 days; 3.3 g. B, Metastasis to lung. Bryan CT 955, pelletized and resuspended in Eagle's basal medium plus 5 per cent calf serum. 1×10^5 pock-forming units; tumour onset 25 days; excised after 13 days; 19.9 g. C, Fibrosarcoma. Bryan CT 951; pelletized and resuspended in Eagle's basal medium plus 5 per cent calf serum; 1×10^5 pock-forming units; tumour onset 17 days; excised 37 days after onset; 3.8 g. D, Strap cells (in centre) suggesting rhabdomyosarcoma in the vicinity of skeletal muscle (not shown in the figure). Bryan CT 951, pelletized and resuspended in Eagle's basal medium plus 5 per cent calf serum. 1×10^5 pock-forming units; tumour onset 18 days; excised after 10 days; 3.2 g.

Ahlstrom and Forsby² using the Schmidt-Ruppin strain of RSV. The latter virus strain was also used in our laboratory as a control and produced similar tumours (Groups D and E, Table 1). In a few instances, metastasis to the lungs was observed (Fig. 1B). In some tumours the cells were sufficiently differentiated to suggest a fibrosarcoma (Fig. 1C). In several cases, when the tumour was invading skeletal muscle fibres, the latter appear to have been transformed to rhabdomyosarcomatous cells (Fig. 1D).

The formation of rhabdomyosarcomatous cells when the tumour produced by either the Bryan or Schmidt-Ruppin strain invades skeletal muscle suggests that the virus can induce several tumour types depending on the tissue infected. This suggestion is further supported by the production of gliomata and choroid plexus papillomata following intracerebral inoculation of the Bryan virus

strain into new-born hamsters⁵ and the production of pleomorphic gliomata following inoculation of the Schmidt-Ruppin strain⁷.

We thank Mr. Stephen Goldberg for his assistance and Drs. W. Ray Bryan, S. E. Stewart and J. C. Landon for their advice. This study was aided by grants from the National Cancer Institute (C-3811) and the Atomic Energy Commission AT (30-1)—910.

IMPLICATIONS OF THE IMMUNOLOGICAL THEORY OF CANCER TO MULTIPLE CAUSES

By DR. MARY R. ANDERSON and PROF. H. N. GREEN

Department of Experimental Pathology and Cancer Research, University School of Medicine, Leeds 2

EXPERIMENTAL neoplasia has been induced in animals by radiation¹, by viruses^{2,3}, and by intrinsic and extrinsic chemical carcinogens. In man, too, these factors have been associated with cancer.

The evidence is still uncertain that the virus is more than a passenger in the cancer cell in man, but the lymphomatous tumour described by Burkitt⁴ among children in Uganda suggests that viruses can cause some types of human cancer. Brookes and Lawley^{5,6} maintain that carcinogens act by altering the nucleic acids binding to the adenine or guanine components of DNA. Gause *et al.*⁷ recently described lesions in the DNA molecule, caused either by ultra-violet light or 5-fluorouracil, which they think are repaired by deoxyguanic and deoxycytidilic acids. X-rays also can cause breaks in the DNA and RNA molecule⁸. Nowell and Hungerford⁹ found loss of a normal chromosome in human myeloid leukaemia; Court Brown *et al.*¹⁰ described the Philadelphia chromosomal abnormality in the bone marrow in myeloid leukaemia, and Upton¹¹ found this Philadelphia chromosome in irradiated bone marrow. So far, no consistent genotype abnormality has been found in malignant cells from fixed tissues¹², although karyotype abnormalities have been found in most cases of chronic myeloid leukaemia¹³, in acute leukaemia¹⁴ and in the bone marrow cells of patients with malignant lymphomas¹⁵. Witts¹⁶ has described an association between the experience of foetal irradiation and the subsequent development of leukaemia, and Holland¹⁷ has pointed out that patients with Down's syndrome (small acrocentric additional chromosome and mongolism) experience eighteen times the national average of leukaemia.

A low concordance for the incidence of cancer in monozygotic twins has been noted, however, which argues against chromosomal abnormality being a direct cause of carcinogenesis¹⁸. Recent work by Rich *et al.*¹⁹ on virus-induced murine leukaemia suggests that aneuploidy results from, rather than initiates, the disease. The observations of Sulzberger, Sherwin and Hermann²⁰ suggest that a chemical could be a carcinogen in one species, and cause contact dermatitis in another. If protein binding were the sole mechanism involved in the aetiology of chemical carcinogenesis by skin painting, one would expect tumour formation in a species such as a rat or mouse where carcinogen-protein binding has been described²¹. In species which do not show protein binding such as the guinea-pig²², the skin would be expected to be inert. Sulzberger has shown, however, that guinea-

pig skin responds by developing contact dermatitis to chemicals which, in other species, cause tumour formation.

The precise site of attack of carcinogens in the chemical induction of cancer is not yet known. Green²³ suggested that carcinogen-protein complexes were formed at lipoprotein sites on the cell surface, and the resultant complexes altered the antigenic nature of the cell, which called forth an immune response from the host. The immune attack deleted, or occluded, the tissue specific antigens on the cell surface, causing a loss of cell identity. He first proposed this immunological theory of cancer in 1954 (ref. 24), when he suggested that loss of identity markers in, or on, the cell (tissue specific antigens) caused a displaced cell to be antigenetically anonymous, and that this anonymity was the fundamental cause of cancer. The maintained loss of tissue specific antigens (TSA) through subsequent cell generations may imply an alteration in the nucleic acids in all neoplasia, such as has been suggested for virus- and radiation-induced cancers. However, this is not necessarily so, as heterologous tumours have been grown for several generations in normal adult animals after having been induced under acquired tolerance²⁵. These tumours re-grew in their species of origin only when induced under acquired tolerance again.

Boyden²⁶ has described a cytophilic antibody which is only elicited to an antigen plus Freund's complete adjuvant, and which adheres to selective cells that can then absorb the antigen. He suggests that this antibody plays a part in the reaction of delayed hypersensitivity, and is normally masked in the serum by excess of classical antibody, which competes for the antigen with that small fraction of cytophilic antibody not attached to the cells. It is thought that any antibody, or antibodies, taking part in carcinogenesis must be similarly masked by the classical responses. It is believed that, in cancer, this antibody, acting on the cell surface, deleting the tissue specific antigens, and rendering the cell anonymous, possibly also modifies the surface membranes so that the malignant cell has a metabolic advantage over normal cells.

There is evidence that malignant cells have all, or nearly all, the species and iso-antigens²⁷⁻²⁹, so the cell surface may have been incorporating serum protein into the cell. The tumours in foreign hosts appeared to have been 'heterogenized' by binding host proteins, and this antigenic alteration was apparently maintained through several generations. It is believed that TSA-depleted cells replicate in a manner similar to these heterogenized tumours,

and that at somatic cell division the nucleus is unable to reconstitute deleted cell components.

Hamburg and Svet-Moldavsky³⁰ altered the antigenicity of trypsinized tumour cell suspensions by virus infection. This antigenic change prevented the tumour growing in normal mice of the strain of origin and caused enhancement in mice pre-immunized with the specific virus. Habel³¹, Sjogren *et al.*³² and Sachs³³ all reported independently on polyoma-induced tumours which could not grow in the pre-immunized strain of origin unless a very large number of tumour cells were injected. This is evidence of malignant cells incorporating a virus which partly alters the antigenic state of the cells so that an injection of a small number of heterogenized tumour cells regressed in a susceptible, pre-immunized host. An injection of a larger number, however, was able to grow and kill the host.

Loss of tissue-specific antigens in tissues undergoing carcinogenic change has been shown to take place³⁴⁻³⁷. If the TSA is deleted it must, presumably, leave a hitherto unexposed site open to immunological attack, and this could, at any rate theoretically, modify the antigenic nature of the cell. It is possible that a structural alteration, resultant on loss of TSA in or on the cell membranes, may also alter the functional behaviour of these membranes. Evidence has been presented to try to demonstrate this alteration in function, which is believed to be immunologically recognizable³⁸. Rat spleen was sensitized to a piece of autologous 20-methylcholanthrene-induced tumour enclosed in a 'Millipore' chamber and replaced intraperitoneally. Cell suspensions were made of the autologous liver and tumour. Autologous tumour and sensitized spleen suspensions were injected subcutaneously into one flank of a guinea-pig, while the other flank received sensitized spleen and autologous liver cells. It was found that the experimental flank showed a larger flare than the control side, thus the sensitized spleen appeared to be capable of recognizing autologous malignant cells. This again suggests some antigenic alteration.

It is believed that there is a structural alteration in the membranes of a malignant cell that can be caused by factors which are endogenous or exogenous to the cell. This is supported by the work of Oppenheimer *et al.*³⁹, who induced sarcomata in rats to subcutaneous implants of strips of 'Cellophane', whereas Goldhaber⁴⁰ did not get sarcomata to subcutaneous 'Millipore' implants, which are porous. A mechanical alteration in the physical environment of the cell caused by an impermeable strip could possibly induce an alteration in the surfaces of adjacent cells, and initiate an immune response.

If an increased permeability to nutrients of the cytoplasmic membranes of malignant cells is postulated, the cell may be working under a metabolic advantage compared with normal cells, which, with the advance of the disease, may possibly cause gradual protein depletion of

the host. This could be one of the causes of cachexia, and of the specific impairment of antibody formation, as compared with other patients, recently described in malignant disease⁴¹.

It is possible that a variety of agents, which act on different cell components including spontaneous gene mutations⁴², find their ultimate expression at the same cell sites and, by inducing an antigenic alteration on the cell surface, initiate an immune response which can culminate in malignancy.

SELF-ADAPTIVE CONTROL AND THE RESPIRATORY SYSTEM

By DR. I. P. PRIBAN and DR. W. F. FINCHAM

Autonomics Division, National Physical Laboratory, Teddington, Middlesex

IN order to design an experimental investigation of a complex biological system it is desirable, if not essential, to have a model or hypothesis which will explain the operation of the system. This is a short report of a study resulting in a hypothesis which offers a simple explanation of the normal behaviour of the entire respiratory control system. Wherever possible the hypothesis is based on structures and mechanisms known to exist.

There are many similarities between the mechanism controlling respiration and those used in the control of some engineering plants. Therefore, engineering concepts have been applied to examine the respiratory system. The main principle underlying the operation of this system is that of self-adaptive control. An adaptive control system (also called self-optimizing) operates by continuously maximizing an over-all performance index in the presence

Fig. 1. Relation between the respiratory variables of blood (based on data from ref. 3)

of major external disturbances. This is achieved by adjusting the characteristics of the system¹.

The respiratory control system may be considered to consist of three interacting control loops. The processes associated with these loops are:

(1) *Chemical control.* The process by which for any given metabolic exchange requirement of both oxygen and carbon dioxide the level of ventilation is kept at a minimum.

(2) *Muscle control.* The process by which for any level of ventilation demanded by the blood chemistry, a pattern of activity of respiratory muscles is selected in which the average expenditure of energy is kept at a minimum.

(3) *Airway control.* The process by which for any alveolar gas exchange requirement the energy required to ventilate the dead space is kept at a minimum.

Each of these processes is co-ordinated and controlled by the over-all controller, a network of respiratory neurones in the brain. The controller predicts the activity which will keep the performance of the respiratory system at its optimum. For this prediction the controller uses information fed back during previous breaths.

Chemical Control

An examination of the physico-chemical properties of blood, in particular of haemoglobin, shows that there is an acidifying (Bohr) effect when haemoglobin is oxygenated in the absence of carbon dioxide. This effect is a function of pH and occurs in the range pH 6-9. It is maximal at pH 7.4 (ref. 2). The presence of carbon dioxide changes this effect. Above certain values of the partial pressure of carbon dioxide, $p\text{CO}_2$, and pH, oxygenation tends to make blood more alkaline³. The presence of carbon dioxide also increases the buffer power towards addition of fixed acid or fixed base. The relation between the function of haemoglobin and the respiratory variables may be represented by the shape of a hill (Fig. 1). This shows that the maximum number of molecules of carbon dioxide that can be exchanged per molecule of oxygen occurs at pH 7.4 and a $p\text{CO}_2 = 40$ mm mercury, the values normally found in arterial blood. Results by Naeraa, Strange Petersen and Boye⁴ suggest that the partial pressure of oxygen, $p\text{O}_2$, is also involved in determining the optimum operating range of haemoglobin. It is likely that at a lower $p\text{O}_2$ the base of the hill is smaller (Fig. 2).

Engineering processes having these characteristics are often controlled by so-called hill-climbers. These are designed to drive the operating point of the process toward some optimum position which maximizes a performance index, for example, minimum operating cost. The mechanism involved basically finds the direction to this position by measuring, for example, the slope of the hill, and uses this information to move the operating point in this direction.

A signal which can be used by the body to define the operating point of the blood are the fluctuations in $p\text{CO}_2$ and pH in the arterial blood produced by breathing. At a constant frequency and depth of breathing these fluctuations are minimal at the optimum operating point and increase on moving away from this (Fig. 2). A theoretical analysis showed that the fluctuations in the arterial $p\text{CO}_2$ increased with increasing metabolic (exercise) carbon dioxide production⁵. It was suggested that these fluctuations and slower ones might have been

signals involved in the control of ventilation. The fluctuations in arterial pH due to breathing that have been recorded in resting man show a swing of 0.01 to 0.015 pH units⁶.

A control system which will keep the blood variables at the optimum values with minimum ventilation is the biological hill-climber shown in Fig. 3. Its goal is to keep the pH- $p\text{CO}_2$ fluctuations at a minimum. The magnitude of the signal in the arterial blood is determined by two factors. One is the mean level of ventilation which determines the position of the operating point. The other is the perturbation due to breathing which causes the fluctuations of pH and $p\text{CO}_2$ in the blood. This perturba-

Fig. 2. The control and functional characteristics of blood

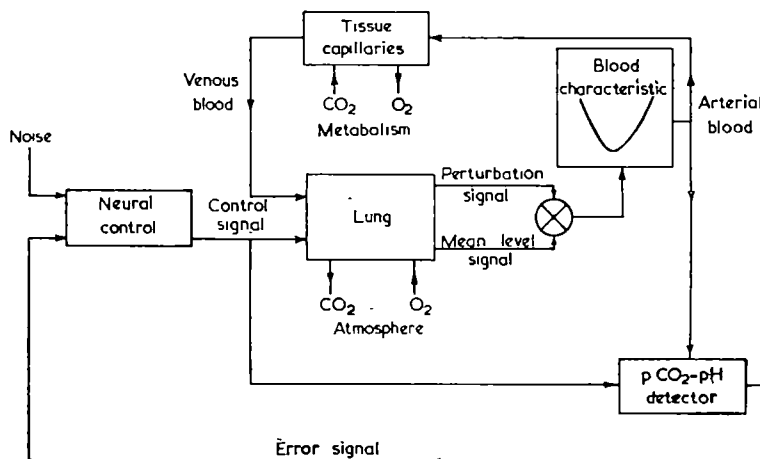

Fig. 3. Control of the respiratory gas exchange. 'Noise' is used to describe signals that are important in keeping the system operational, but which have no relevant control component

on signal $f(p\text{CO}_2, pH)$, and a signal which is a function of the signal controlling breathing are combined in the detector to give an error signal. The control signal input to the detector is necessary to give the sign of the error signal and also to make allowance for changes in the depth and frequency of breathing. The natural choice for the detector is the area postrema. The relevant factors are its structure, its closeness to the medullary respiratory neurones and the relative absence of the blood-brain barrier in the area. The error signal from the detector is fed back to the neural control where the control signal is corrected in the direction that will take the operating point of the blood towards the optimum. This control will keep the ventilatory gas exchange equal to that required by the metabolism of the body.

In order that this control can be effective (in particular that associated with the perturbation signal due to breathing) it is necessary that the noise-level in the mixed venous blood, of which the random fluctuation about the mean level of the $p\text{O}_2$ is a component, is kept at a minimum. This would be accomplished if the proportion of the cardiac output distributed to a particular region were a function of the metabolism in this region. Such control will optimize the respiratory function of the circulation. Receptors of the type found by Hughes⁹, lying on the venous side of any tissues, could be part of the control mechanism which accomplishes this control. The adjustment of the peripheral circulation through the corresponding tissue would be via the autonomic nervous system.

The brain is without an oxygen store and its metabolism is essentially aerobic, so that its functioning is critically dependent on a satisfactory oxygen supply. The arterial chemo-receptors lying in the circulatory path to the brain would seem to be in the most suitable position to detect any potential lack of oxygen supply to the brain and bring about a feed-forward compensatory adjustment to the cerebral circulation and to the cardiac output generally as well as influencing respiration. This emergency type control mechanism is considered to bring about a rapid qualitative (coarse) adjustment which over-rides the optimizing control mechanism discussed.

Muscle Control

The muscles that are used for breathing may also be involved in maintaining posture or in producing movement of the trunk and limbs. Taking up a new posture or movement of limbs may result in a new pattern of breathing, for example, a new frequency of breathing and/or a new mean thoracic volume. The response usually takes a few breaths to settle down and is associated with a different spatial and temporal distribution of muscle activity.

This aspect of respiratory control involves muscle spindles and spinal cord structures. It has received considerable attention¹⁰⁻¹² since Nathan and Sears¹³ showed its importance in normal breathing. The general arrangement of the structures is shown in Fig. 4.

The behaviour of this sub-system may be described in terms of a number of time-varying contours. One set of

Fig. 5. Neuro-muscular control system

contours represents values of muscle activity on the grid of a muscle map (Fig. 5). The physical properties and the structure of the chest respiratory apparatus are such that progressively more energy is required for operation towards the extremities of the system. This property is represented by contours of performance index values on the muscle map. The performance index is defined in terms of the maximum number of units of ventilation obtainable per unit energy expenditure in the respiratory muscles. The contours are different for different levels of ventilation and different postures. The function of the control process is seen as the matching of the muscle activity contours with the performance index contours of highest value.

The highest level of control is the neural respiratory activity in the brain as represented by brain activity contours. The nervous activity is seen as equivalent to energy, for it is the signal determining the instantaneous energy expenditure during a breath and the duration of a breath. Once a breath has begun this control activity is not modified during natural breathing. The muscles that are activated are selected by a scanning process involving the fusimotor (γ -loop) system (Figs. 4 and 5). The scanning process selects the route of activation by a continuous appraisal of the muscle tension as determined by the muscle spindles. In this way the output from the spindles determines the spatial distribution of muscle activity. The muscles with the maximum performance index correspond to those in which the spindle output is at a minimum. This scanning process probably involves a low-amplitude 10-c/s component of muscle activity.

The process selects the optimum pattern of respiratory muscle activity by making the best

Fig. 4. Idealized structure of the neuro-muscular respiratory system

choice of inspiratory and expiratory muscles to be activated. It does this even when some of the muscles concerned with respiration are also involved in producing movement or maintaining posture.

The spindles also feed back information to the brain¹⁴. If the muscles shorten according to the predicted control signal then the muscle tension corresponds to the electrical activity. In this condition the ratio of the signal output from the spindles to the input to both muscles and spindles is unity and no correction of the brain activity (which determines the pattern of the next breath) is necessary. If, however, the load on the muscles has changed, the information fed back alters correspondingly. This informs the brain about the new state of the muscular system and enables it to make a new prediction of the optimum activity.

Airway Control

Temporary blocking of the vagus nerve causes an increase in the variance of the depth and frequency of breathing¹⁵. This implies that the energy consumption was increased for the same level of ventilation. The vagus nerve carries both the efferent fibres to the smooth muscles in the airway walls and afferent fibres coming from the receptors in the airway walls¹⁶.

From the structure and behaviour of the respiratory system one can predict that the function of the airway control mechanism is to keep the airway diameter adjusted, by means of the smooth muscles, to those dimensions at which the forces acting on the walls of the airway due to the main muscles, are minimal. The brain activity and corresponding activity in the vagus nerve are seen as determining the size of the airway diameter at any instant

relative to the activity of the main respiratory muscle. The purpose of the airway control process is to attain the condition of the airways in which the energy required to both ventilate the dead space and overcome airway resistance is minimal. The process controlling this optimization must, therefore, interact with the chemical control and muscular control mechanism.

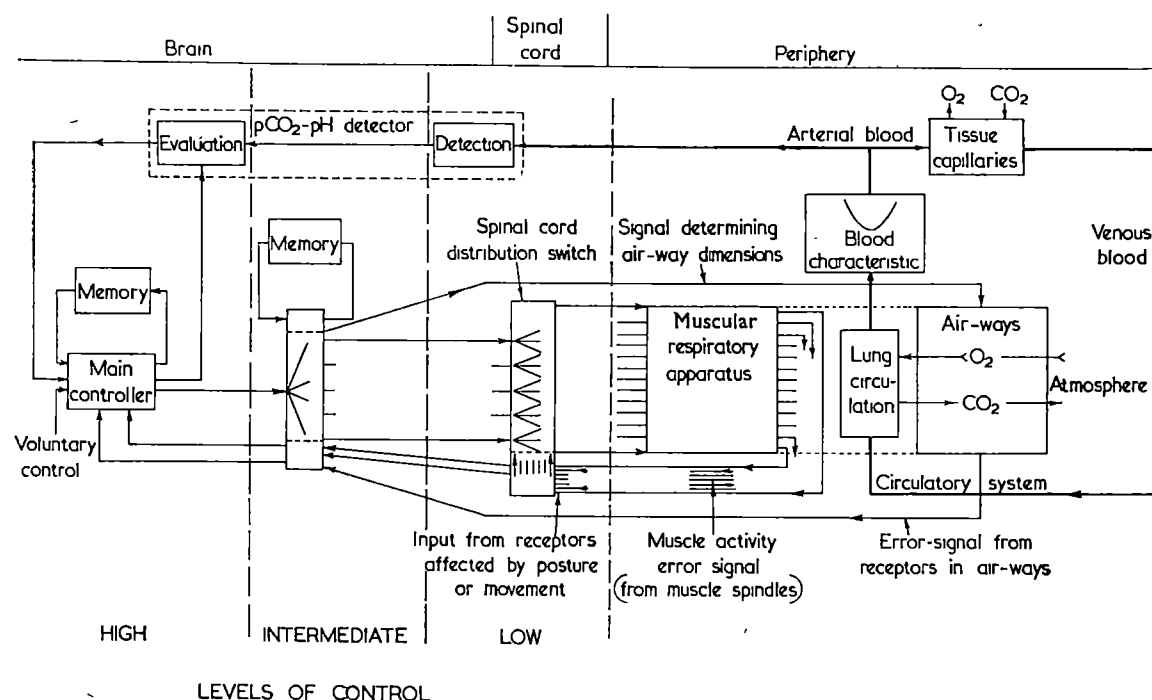

Over-all Control of Respiration

The function of the over-all control process is the combination of the functions of the three sub-systems—that is to regulate respiration so that this is accomplished with the minimum consumption of energy. The control ensures that the ventilatory gas exchange and the metabolic gas exchange are equal.

The control action of the entire system is seen as being divided according to their importance into three levels of control (Fig. 6). A high level defines the total amount of energy, E , to be expended in a breath and the time, τ , over which it is to be dissipated. It does this by evaluating the optimal predicted activity of a breath with the actual activity in that breath. The result is the prediction of the next breath in terms of energy and time.

The optimal prediction by the high-level controller is the activity that should keep the operating point of the blood at the optimum while using a minimum of energy. The prediction is conditioned by the response of the system during previous breaths.

An intermediate-level controller interprets the orders from the higher level and produces a more detailed temporal distribution of the pattern of activity. It also produces some spatial resolution of activity. A low-level

High	Intermediate	Low
Prediction of the total energy, E , to be expended in the next breath in terms of duration, τ , tidal volume and airway diameter	Increase in resolution of E in time τ and in coarse resolution of E in space.	Detailed resolution of E in space
Data reduction and storage.	Assessment in time of muscle activity accomplished	Assessment in space of muscle activity accomplished
Assessment of operating point on blood characteristic		Detection of amplitude of signal $f(pCO_2, pH)$

Fig. 6. Organization of structure and function of the over-all respiratory control system

controller accomplishes the fine spatial resolution of activity. This resolution has also a small temporal component.

Consider a control sequence: a change in the operating point of blood may be the result of a change in: (1) ventilation; (2) metabolism; (3) efficiency of airway control. The chemical detector mechanism effectively determines both the magnitude and the direction of the operating point of blood from the optimum value. It does this by comparing the chemical state of the blood in the last few (probably two) breaths with that in earlier breaths. The purpose of the comparison is to decide whether or not a change of respiratory energy dissipation is required to change ventilation.

In order to resolve ventilation into tidal volume, V_t , and breath duration, τ , the main controller uses the previous prediction, that is, the memory of the activity controlling the present breath and the error signals fed back from the muscular sub-system and airway sub-system. These error signals contain the information about the mismatch in performance with respect to the best input to the sub-system. These data are reduced at the low and intermediate level controllers so that only the significant information about the accuracy of the prediction is fed back to the main controller.

The prediction and relative adjustment of the values of V_t and τ at which the mean value of E is at a minimum (for a given ventilatory demand) involve information passing around the control loops in the three sub-systems. That such a control process exists is suggested from an analysis of small variations in V_t and τ which have been observed during breathing¹⁷. The values of V_t and τ are positively correlated. The average cycle time for these variations is 3.6 breaths, while the cycle time expected from a random process is 3 breaths. The shortest cycle time of a search process of a controlled system of the type discussed in which there are delays and which is subjected to random disturbances would be expected to have a length of 3-4 breaths.

The function of any sub-system or component of the respiratory system can be represented by contours having values of a functional index, as was done for the respiratory muscles. The index contours of many, if not all, structures take the form of a hill. The over-all purpose of the control is to regulate the different functions so as to obtain coincidence of the hills representing the different components. In other words the individual component systems are adjusted so that these operate at their optima. By combining the hills representing different structures the map of functional index contours of the entire system is obtained. In this context the over-all control should be seen as a hill-climbing process involving an over-all functional hill of the respiratory system.

The nervous activity associated with a conscious voluntary effort is seen as over-riding the self-optimizing control process for a short period. Similar nervous activity is thought to produce the sharp rise in ventilation at the beginning of exercise¹⁸. The immediate response would

seem to be a very qualitative increase in tidal volume (or E). This may be seen as a feed-forward signal anticipating an increase in ventilatory requirement. The adjustment of the total level of ventilation V_t and τ to the optimum values can then occur in the usual time. The selection of the optimal pattern of respiration for a new posture or during movement also involves the spinal mechanisms and muscle receptors (Fig. 6). This aspect is more complex than has been implied here. More details about the structures and mechanisms involved have been discussed by C. von Euler¹¹.

Only the essential points have been presented here to describe a new way of thinking about the organization and mode of operation of the respiratory control system. The underlying principle of operation, the maximization of an average functional index, may be applied to the study of most complex systems, even to the entire living organism. Certain of the aspects of respiratory control are discussed elsewhere in more detail and in relation to new experimental findings¹⁹. The relevance of this type of investigation to understanding such aspects of respiratory impairment as those producing the sensation of breathlessness are also discussed elsewhere²⁰.

We thank Dr. A. M. Uttley, superintendent of the Autonomics Division, National Physical Laboratory, for providing facilities at the laboratory, and Mr. P. H. Hammond for initiating and guiding this interdisciplinary investigation.

REACTION OF HUMAN LYMPHOCYTES IN CULTURE TO COMPONENTS OF THE MEDIUM

By G. J. JOHNSON* and PROF. P. S. RUSSELL

Department of Surgery, Harvard Medical School, and General Surgical Services, Massachusetts General Hospital, Boston, Massachusetts

THE *in vitro* lymphocyte transformation reaction has already found many applications^{1,2}. In the hands of Bain, Vas and Lowenstein³, and Bach and Hirschhorn⁴ it has been shown to be potentially of use for histocompatibility matching in human beings. However, in order to

be able to discriminate between members of a family when choosing a suitable donor for tissue transplantation, fine degrees of difference in stimulation of lymphocytes must be capable of detection.

Early in the development of this system for human histocompatibility testing, using a modification of Hirschhorn's technique⁵, it was found that an unexpectedly

large number of blastoid cells and mitoses occurred in the control culture tubes, that is, those tubes in which the lymphocytes of one individual were cultured alone in the medium for 7 days. The present experiments were designed to investigate the hypothesis that these 'high control counts' might represent a primary immune response to various constituents of the medium.

The semi-purified lymphocytes used in these experiments were prepared from 50 ml. of venous blood drawn into a syringe containing 3 ml. of heparin (1,000 units/ml.). Gelatine ('Plasmagel') was added in the proportion of 1 : 2.5 of blood, and mixed in 50-ml. centrifuge tubes, inclined at 45°. After 40 min the red cells were sedimented. The supernatant, containing white cells and gelatine in addition to plasma, was transferred to 100-ml. bottles, and a knife-point of iron powder⁷ added. These bottles were incubated at 37° C, with agitation, for 1 h. The plasma was then spun in 15-ml. tubes in an International Clinical Centrifuge at 400 r.p.m. for 3 min. At this speed almost all those granulocytes which had engulfed iron-particles were sedimented. The remaining cells were then obtained from the supernatant by centrifugation in new tubes at 1,850 r.p.m. for 4 min, washed with Eagle's medium, and counted. The majority of these cells were typical small lymphocytes but there was an average granulocyte contamination of 38 per cent.

The cells were grown in 110 mm × 16 mm culture tubes, tightly closed, in a medium consisting of Eagle's minimal essential medium with 20 per cent foetal calf serum, 1 per cent L-glutamine (200 mM) and 125 units penicillin and 125 γ -streptomycin/ml. For each subsequent variation in the medium there were 2 parallel tubes and also phytohaemagglutinin ('Difco M') controls.

The cells were developed after 7 days by treatment with 1 per cent sodium citrate solution (to separate the clumps of cells) and fixation in 25 per cent glacial acetic acid in absolute ethyl alcohol. A minimum of 1,000 cells, fixed on slides and stained by Jenner-Giemsa, were counted microscopically by a standardized technique. One person counted the whole of one experiment without knowing the identification of the slides. The percentage of large cells plus the percentage of mitoses were added to give the 'percentage of change'. The final result was the average of the counts of 2 parallel tubes.

A few of the large cells possessing large, pale nuclei with two or three nucleoli had a grey cytoplasm which differed from the densely basophilic cytoplasm of the typical lymphoblasts. These cells were considered to be macrophages. Some other cells could not be put into either category. Therefore, all these cells with large nuclei which were clearly of a different size and type from those of the small lymphocytes were counted together as 'large cells'. The great majority of them, however, were typical lymphoblasts.

In the first 30 normal individuals it was found that the percentage of change in control tubes containing the total medium ranged from 5.0 to 48.0 per cent, with an average of 17.2 per cent.

This variable but high count in the controls was at first ascribed to the granulocyte contamination. However, the percentage of enlargement bore no relation to the percentage of granulocytes in each lymphocyte preparation. Even a 99 per cent pure lymphocyte preparation from peripheral blood gave an 11 per cent change when grown alone in the medium.

Therefore, the possibility that the 'high control counts' represented a primary immune response to various constituents of the medium was tested by deleting these constituents in a step-wise fashion. The foetal calf serum was replaced by new-born calf serum from which the γ globulins had been removed⁸ or autologous human serum (prepared from fresh clotted blood), and the penicillin and streptomycin mixture was also removed. The resultant step-wise reduction in counts in six different individuals is shown in Table 1.

Except in two instances where duplicates were not completed, each compartment in Table 1 represents the mean of two assays. The two assays obtained for these 23 pairs were tested to determine whether chance circumstances could account for discrepancies which existed or whether unknown factors were responsible. Separate χ^2 values on the original cell counts computed by a four-fold contingency table from 13 pairs totalled 16 (degrees of freedom = 13; $P > 0.1$). The remaining 10 pairs each had large χ^2 values, suggesting that the assays were not true duplicates.

Therefore, in subsequent comparisons to determine the significance of the effect produced by foetal calf serum or penicillin and streptomycin, the only cell counts used were those derived from pairs where good agreement existed.

In considering the effect of the presence of foetal calf serum in the medium instead of autologous serum, 4 comparisons between 8 compartments revealed a highly significant difference ($\chi^2 = 1.100$; $d.f. = 4$; $P < 0.001$). Similarly, 4 comparisons of the values in the presence and absence of penicillin and streptomycin were also significant ($\chi^2 = 52$; $d.f. = 4$; $P < 0.001$).

The values obtained when $\alpha\gamma$ -globulin calf serum was used were among those in which less satisfactory agreement between the duplicate assays was found. Therefore, in comparing these results with those for foetal calf serum on one hand, or autologous serum on the other, the assay selected to represent the $\alpha\gamma$ -globulin serum was the one of the pair which was closest to the value with which it was being compared. This selection provided the least favourable value for demonstrating differences between the $\alpha\gamma$ -globulin serum and adjacent compartments. Despite this conservative method of analysing the data, the differences for 4 comparisons in each direction are significant (for each $\chi^2 > 120$; $d.f. = 4$; $P < 0.001$).

At first glance the criticism might be raised that these results could be accounted for on the basis of nutrition: that foetal calf serum is a better nutrient than $\alpha\gamma$ -calf serum or autologous human serum. There are three reasons for thinking that this is not the case.

(1) The percentage of cells which are transformed by three days under the influence of phytohaemagglutinin is consistently greater when the medium contains autologous serum than when it contains foetal calf serum.

(2) In other experiments in which cells sensitive to tuberculin or Candida antigen are stimulated by these antigens, the net count (the count in the stimulated culture minus the count in the controls) is greater when the medium contains autologous serum than when it contains foetal calf serum.

Both these results suggest that the autologous serum is in fact a better nutrient than is foetal calf serum.

(3) The addition of penicillin and streptomycin to the medium significantly increased the percentage of large cells and mitoses. It would seem to be more likely that these antibiotics are acting as antigens or as stimulants, than that they improve the nutritive properties of the media.

In the experiments in Table 1, a semi-purified lymphocyte preparation was used; however, if the same type of experiment was attempted using the total white cells present in the supernatant after sedimentation of the red cells with gelatine, the results were more erratic; the step-

wise reduction could not always be produced; and the spontaneous enlargement in the absence of foetal calf serum and antibiotics could not be reduced to such a low level.

It is possible that, in addition to the components of the medium, white blood cells other than small lymphocytes and granulocytes play a part in producing the 'high control count'. McFarland and Heilman⁹ have recently reported their observations on living cultures which suggest that the macrophages play an important part in the transformation of lymphocytes to lymphoblasts. The preparation of the semi-purified lymphocytes used in the experiments reported here involved a stage of incubation and mild agitation with iron powder. This was followed by centrifugation at low speed. Examination of both the sediment and supernatant from this centrifugation reveals that the supernatant contains the nuclei of disrupted monocytes. Almost all the monocytes are removed from the lymphocyte preparation, not by engulfing iron and being sedimented, but by destruction. Monocytes, which are present in greater numbers in the total white blood cell preparations, may cause, or permit, a spontaneous enlargement in the cultures which is not so clearly controlled by alteration of the constituents of the medium.

A similar 'high control count' has been observed with the total white blood cells of the rat in culture. Unlike the human situation, these counts could not be reduced by subtraction of foetal calf serum or penicillin and streptomycin. These experiments have not yet been repeated with purified lymphocytes.

The time curve of the reaction of human lymphocytes to foetal calf serum shows that there is an upswing at 7-8 days. By contrast, the reactions of lymphocytes from individuals sensitive to PPD or Candida antigen, when cultured with these antigens, show their main response at five to six days. It may be that this difference in the time of development of large cells reflects the difference between a primary and secondary immunological response

of the lymphocytes. If that were the case, the reaction to foetal calf serum would be a primary response.

Another observation emerges from these experiments. This is the apparent 'summation' effect produced by the addition of antigens. The impression is gained that the addition of antigens of different specificity causes additional lymphocytes to become involved in the reaction. A similar observation was made by Chapman and Dutton¹⁰ in rabbits. The responses of lymphoid cells from immunized rabbits to the simultaneous presence of the immunizing antigen (heterologous serum protein) and allogeneic lymphoid cells was greater than the response to either alone.

These results are encouraging from the point of view of the application of this system to histocompatibility testing. It is reasonable to think, from what has already been shown, that allogeneic lymphocytes which differ from each other by two antigens of the same strength would stimulate one another to a greater extent than if they were to differ at only one of the two sites.

It is hoped that the avoidance of substances in the medium which, by themselves, will stimulate the lymphocytes to enlarge and divide will make it easier to detect minor differences in antigenicity between potential allograft donors.

AFLATOXIN: EFFECT ON CULTURED HETEROPLOID HUMAN EMBRYONIC LUNG CELLS

By DR. MARVIN S. LEGATOR, SAVERIO M. ZUFFANTE and ANTHONY R. HARP

Bureau of Scientific Research, Division of Pharmacology, Tissue Culture Section Food and Drug Administration, U.S. Department of Health, Education and Welfare, Washington, D.C.

AFLATOXIN, a mixture of metabolites produced by *A. flavus*, has been characterized chemically^{1,15}, and sensitive methods for the detection of the major aflatoxin components have been reported^{4,7}. In certain sensitive animal species this group of mycotoxins is acutely toxic at low concentrations, usually showing hepatotoxicity. In addition to its acute toxicity, aflatoxin B₁ is an exceedingly potent carcinogen in rats⁸ and trout². In biological studies the major effort has been directed towards the development of bioassays to augment and confirm the chemical procedures of analysis. There have been few reports on the biological action of this group of toxins and only three reports on the action of aflatoxin in *in vitro* systems. Juhasz and Greezi found that low concentrations of various groundnut samples destroyed cultured calf kidney cells⁹. Smith found that the toxicant inhibited the incorporation of ¹⁴C-leucine into protein in various liver preparations¹³; Legator and Withrow reported that the crude and crystallized aflatoxin preparations suppressed mitosis in cultured human diploid and heteroploid embryonic lung cells¹⁰. The experiments reported here were designed to expand the information concerning the biological activity of aflatoxins in cell

culture. The effect of aflatoxin on cell growth, cell morphology, and the synthesis of DNA was investigated.

A heteroploid human embryonic lung cell line, L-132, was used. The cells were cultured in monolayer, using basal medium (Eagle) with Earle's 'BSS' and 10 per cent calf serum. Aflatoxin was added to the growth medium by one of the following procedures:

(1) The chemical was dissolved in propylene glycol and added directly to the culture medium. The amount of solvent in the culture medium never exceeded 0.1 per cent; this concentration in preliminary experiments was ten times below any detectable toxic concentration.

(2) The aflatoxin preparation was dissolved in chloroform and added to the culture vessel. The chloroform was removed under nitrogen and sterile medium was added.

Usually, to achieve maximum solubility, the uninoculated medium containing the toxicant was sonicated in a Branson 'S-75' unit for 30 sec. After sonication the medium was inoculated with approximately 100,000 cells per c.c. of medium. The cells were incubated at 37° C in an atmosphere of 3 per cent carbon dioxide.

Cell growth in the presence of aflatoxin. To determine the effect of aflatoxin on cell growth, cells were counted by a Coulter counter, and protein and DNA were determined. An aflatoxin preparation (495) containing 15 per cent aflatoxin B_1 , 9 per cent G_1 and less than 1 per cent B_2 and G_2 was used. The final concentration added to the culture vessel was based on the known concentration of B_1 and G_1 in this preparation. Up to the 48th hour after the addition of the toxicant, cells exposed to 0.05, 0.1, 0.5 and 1.0 p.p.m. increased in number; the 0.05 p.p.m. concentration differed very little from the control. There was little increase in cell numbers between 48 and 93 h at 0.05, 0.1 and 0.5 p.p.m. At 1.0 p.p.m. there was a slight decrease in cell numbers. During this same period of incubation the cells in the control divided rapidly. At the highest concentration used, 5.0 p.p.m., there was an entirely different response, since only a negligible amount of growth was found at any of the time-intervals investigated. Fig. 1 summarizes the results of this experiment.

DNA was determined according to the method of Webb and Levy¹⁶; protein was assayed according to the method of Lowry *et al.*¹¹. The DNA and protein determinations essentially confirmed the results obtained with the cell count determination. Fig. 2 indicates the effect of 0.5 p.p.m. on protein content when the cultures were examined over an incubation period of 4–93 h.

To determine the viability of the cells after various time exposures to aflatoxin, trypan-blue was used as a vital stain. No difference was found in viability between the control and the cells exposed to the toxicant except at the concentration of 5.0 p.p.m.

Morphology and giant cell formation. The L-132 cells exhibited many abnormal morphological patterns including

Fig. 1. Effect of aflatoxin on cell growth: cell count by Coulter counter

Fig. 2. Effect of aflatoxin on cell growth: total protein determination

Fig. 3. Giant cells, showing vacuoles after exposure to aflatoxin, 1 p.p.m.

vacuolization and an accumulation of cellular debris. Cell vacuolization was similar to the response reported by Smith in monolayer growth of monkey kidney cells¹². In addition there was an abnormally high number of giant cells. Fig. 3 illustrates a typical giant cell showing cell vacuolization after an exposure to 0.1 p.p.m. of aflatoxin. To determine the number of giant cells, cells were trypsinized and fixed in acetic acid-ethanol (1:3) and stained with 1 per cent toluidine blue. Approximately 4,000 cells were counted to determine the number of giant cells in the population. The normal population contained approximately 0.3 per cent giant cells. After an exposure of 8–12 h to 1 p.p.m. crystallized aflatoxin B_1 , a 92 per cent increase in giant cells was found over the control. To determine the persistence of giant cells after exposure to the toxicant, L-132 cells were exposed to 1 p.p.m. of aflatoxin (495) for 24 h. After this exposure period the medium containing the toxicant was removed and fresh medium minus the toxicant was added. The number of giant cells was then determined at various time-intervals after the removal of aflatoxin. After a 24-h exposure to aflatoxin, followed by removal of the chemical, an 81–100 per cent increase in giant cells was found for a period up to 10 h. From 12 to 24 h after the removal of the toxicant, proportionately fewer giant cells were found. Table 1 shows these results.

Autoradiographic studies. To determine the effect of aflatoxin on DNA synthesis, tritiated thymidine was employed. The labelling procedure was essentially that of Moorhead and Defendi¹³. The cells were incubated in the presence of aflatoxin for 16 h before 'pulsing'. The cells were then exposed for 20 min to tritium-labelled thymidine at a concentration of 0.5 µc. per ml. The medium was removed and replaced with 50 per cent fresh medium and 50 per cent of the medium that had been removed before pulsing. After a further 12 h the cells were removed, fixed and dipped in NTB2 liquid emulsion (Eastman Kodak Co., Rochester, N.Y.), and the slides were incubated for 10 days before being developed.

Fig. 4. Inhibition of DNA synthesis after 16 h exposure to aflatoxin

Fig. 5. Inhibition of incorporation of tritiated thymidine into DNA after exposure to aflatoxin, 1 p.p.m., for various time intervals

The number of labelled cells was determined, a minimum of 1,000 cells being counted for each determination. In this study the aflatoxin (495) and crystallized aflatoxin B₁ were used. A 40 per cent inhibition of DNA synthesis was produced by 0.1 p.p.m. of B₁ and more than 80 per cent inhibition of DNA synthesis by 1 p.p.m. of aflatoxin (495). The crude aflatoxin (495) at 1 p.p.m. was more effective than 1 p.p.m. aflatoxin B₁. The results of this experiment are summarized in Fig. 4.

Fig. 5 shows the inhibition of DNA synthesis after exposure of cells to 1 p.p.m. aflatoxin (495) for various time-intervals from 4 to 12 h. During this period, DNA synthesis was reduced by 4–84 per cent.

Discussion. A probable sequence of events for the effect of aflatoxin on this biological system can be constructed, based on the present investigations and the previous work

on mitotic suppression⁹. The earliest effect of this toxicant is to suppress DNA synthesis and mitosis; this effect is detectable within the first few hours after exposure of the cells. The inhibition effect on division and DNA synthesis leads to the survival of the cell in a non-dividing stage which can be quantitated after 48 h of exposure to aflatoxin. In the static population there is no equilibrium between the lethal effects of the chemical and the number of dividing cells. This has been shown by the viability counts. The abnormal production of giant cells could well be accounted for by the enlargement of non-dividing cells. The giant cell formation seems to be of the non-syncytial type seen in tissue culture cells infected with certain viruses, and is associated with cells in which mitosis has been arrested in metaphase³.

The suppression of mitosis, inhibition of DNA synthesis, and formation of giant cells in this system, as well as the previously reported carcinogenic action of aflatoxin, may well indicate that aflatoxin affects biological systems much as do known alkylating agents. Alkylating agents that are chemically reactive compounds are known to interact with nucleophilic (electron-rich) centres of receptor molecules of the cell⁸. Dickens and Jones have shown that aflatoxin, as well as other chemicals that contain an α - β unsaturated lactone ring, are carcinogenic⁵. It is possible that this functional group may be responsible for the overall biological effect of aflatoxin.

Alkylating agents are known to be mutagenic, carcinogenic and anti-neoplastic⁶. The carcinogenic effect may well be a manifestation of the mutagenic action^{6,14}. If aflatoxin is a unique alkylating agent, the demonstration of mutagenicity and evaluation as a candidate anti-neoplastic agent may be the next steps in investigating its biological effects.

NICOTINAMIDE MONONUCLEOTIDE PYROPHOSPHORYLASE ACTIVITY IN ASCITES CELL EXTRACTS

By PROF. L. S. DIETRICH, L. FULLER, I. LEONOR YERO and LAURA MARTINEZ

Department of Biochemistry, University of Miami School of Medicine, Florida

NICOTINAMIDE MONONUCLEOTIDE (NMN) pyrophosphorylase activity has been detected previously in acetone powder extracts of erythrocytes¹ and ascites cells². In both these cases, the *K_m* for the nicotinamide was extremely high, being 0.1 M and approximately 0.1 M for the erythrocyte¹ and ascites acetone powder extracts², respectively. The very low affinity for nicotinamide would seem to indicate that the physiological role of this enzyme in the biosynthesis of nicotinamide adenine dinucleotide from nicotinamide is doubtful. Work in our laboratory has shown that the

supernatant fluid obtained from ascites cells homogenized in a tris-chloride buffer contains NMN-pyrophosphorylase. The enzyme, in this crude form, has a *K_m* for nicotinamide of 1.6×10^{-5} M and requires adenosine triphosphate (ATP) as well as 5-phosphoribosyl-1-pyrophosphate (PRPP).

Ehrlich-Lette ascites cells were grown in Swiss albino (Webster) mice, 2–3 months of age. Cells were gathered 7–10 days after incubation and collected in heparinized vessels. Pooled cell suspensions were centrifuged at 600g for 5 min at room temperature and the supernatant

fluid discarded. The cells were resuspended in 6 volumes of isotonic NaCl solution and the washing procedure repeated four times to remove contamination erythrocytes. The cells were then suspended in 9 volumes of 0.05 tris-chloride buffer, pH 7.3, and homogenized for 1-2 min employing a homogenizer of the Potter-Elvehjem type. The supernatant fluid obtained by centrifuging this homogenate at 21,500g for 30 min served as the enzyme source.

Assay of NMN-pyrophosphorylase activity. Reaction mixture contains: 0.3 ml. of ascites supernatant, 0.7 μ moles PRPP, 2.0 μ moles ATP, 10 μ moles $MgCl_2$, 0.1 μ moles nicotinamide- ^{14}C (8.0 $\mu c./\mu$ mole) and 50 μ moles of tris, pH 7.3, in a total volume of 1 ml. Incubation was carried out at 37° C for 1 h, at which time the reaction was stopped by heating in a boiling water bath for 1½ min. The samples were then centrifuged and the supernatant material was chromatographed in paper employing the solvent C of Preiss and Handler³. The areas corresponding to NMN were cut out and counted in a liquid scintillation spectrometer as previously described⁴.

The requirements for the NMN-pyrophosphorylase activity of ascites cells is shown in Table 1. Mg^{++} , PRPP and ATP are required for the complete reaction. Stimulation produced by ATP appears to be specific, not being replaced by guanosine triphosphate (GTP), uridine triphosphate (UTP), and cytidine triphosphate (CTP) or the di- and mono-adenine derivatives.

Identification of enzymatic product as NMN. The reaction product obtained has been characterized employing four different paper chromatographic systems: the solvent B and C of Preiss and Handler³, isobutyrate-ammonia⁵, and N-butanol saturated with water in an NH_4HCO_3 atmosphere⁶ and paper electrophoresis. Under these conditions the unknown behaved in an identical manner to NMN. Mild alkaline hydrolysis with NH_4OH resulted in the release of a radioactive compound that behaved in an identical manner to nicotinamide in the aforementioned chromatographic and electrophoretic procedures.

A Lineweaver-Burk plot of the NMN-pyrophosphorylase activity in ascites cell supernatant employing nicotinamide as substrate is presented in Fig. 1. The K_m for nicotinamide calculated from these data is 1.62×10^{-5} M.

Optimum-pH experiments for the enzyme under these conditions demonstrate that the enzyme has a broad peak exhibiting maximum activity from pH 6.5 to pH 9. No attempt was made to determine whether the decrease in activity at either side of the broad activity peak is revers-

NMN Pyrophosphorylase in Ascites Cells

Fig. 1. Lineweaver-Burk plot of pyrophosphorylase activity employing nicotinamide as substrate

ible. However, exposure of the enzyme to a pH of 4-8 for short period of time does irreversibly inhibit the enzyme.

Under the condition of the assay the enzymatic activity is proportional to enzyme concentration and time of incubation. The effect of various inhibitors and treatment on the activity of NMN-pyrophosphorylase activity of ascites cells is presented in Table 2. The enzymatic activity is destroyed by boiling, freezing or exposure to cold acetone. It is inhibited by phosphate and pyrophosphate. The enzymatic activity is stable to storage at 4° C overnight at 55° C for 1 min. No activity was lost during protamine sulphate treatment of the supernatant. The activity of whole homogenate is considerably less.

The presence of an enzyme capable of converting nicotinamide to NMN in the presence of PRPP and ATP with a K_m for nicotinamide of 1.6×10^{-5} M is significant and demonstrates that these cell types possess the enzymatic capacity to convert nicotinamide directly to NMN without necessitating deamidation of nicotinamide to nicotinic acid⁷ and the subsequent utilization of the Preiss-Handler pathway³ to NAD. The ascites cells studied contain endogenous nicotinamide levels of approximately 4 μ moles/g wet weight (unpublished data). Thus, it is feasible that this reaction could, in the absence of inhibitors, proceed at a significant rate in intact cells.

The marked stimulation of NMN-pyrophosphorylase activity by ATP is similar to that observed for nicotinic acid mononucleotide pyrophosphorylase activity⁸. Whether the function of ATP is to control the direction of the reaction, as has been recently demonstrated by Nakamura *et al.*⁹ for nicotinic acid mononucleotide pyrophosphorylase, remains to be determined.

Evidence that NMN-pyrophosphorylase is not the same enzyme that catalyses the conversion of nicotinic acid to nicotinic acid mononucleotide is demonstrated by the fact that NMN-pyrophosphorylase is irreversibly inactivated at pH 4.8 while the nicotinic acid mononucleotide pyrophosphorylase activity of the extract remains unaltered.

MATURATION IN VITRO OF MOUSE, SHEEP, COW, PIG, RHESUS MONKEY AND HUMAN OVARIAN OOCYTES

By DR. R. G. EDWARDS

Physiological Laboratory, University of Cambridge

THE investigation of early development in many mammalian species is restricted by the difficulty of obtaining sufficient numbers of oocytes and embryos at particular stages of development. Post-dietyate ovarian oocytes are usually obtained after stimulation by luteinizing hormone (LH) either during the female cycle or after the injection of exogenous hormone, and ovulated eggs can be obtained in relatively large numbers after super-ovulation treatments. While these methods are highly satisfactory for many types of investigation, they are obviously unsuitable in the examination of species such as primates or man where the effect of exogenous hormones is undesirable or inadequately understood and in experiments demanding very large numbers of oocytes. An alternative technique has been reported in rabbits¹ and rodents², namely, to liberate the oocyte from its follicle into a culture medium whereon the prolonged dietyate stage is abruptly terminated, the germinal vesicle breaks down, and meiosis is resumed at diplotene/diakinesis within 2-3 h. But, with dog, primate and human oocytes, the germinal vesicles persisted after 20 h of culture³. The results of the present work indicate, however, that in many if not all mammalian species the culture of liberated oocytes for periods longer than 20 h will induce a resumption of meiosis at a rate exactly comparable to that occurring *in vitro* after an injection of LH into the mother. With this technique it should eventually be possible to study pre-ovulatory development, and perhaps fertilization and pre-implantation development in various species including man.

Maturation of Oocytes *in vitro*

Oocytes from mice, pigs, cows, sheep, monkey and man were liberated from their follicles into a culture medium containing heparin to prevent clotting of the follicular fluid, and then cultured in various media: Waymouth's Medium MB 752/1 (ref. 3), Medium 199 (ref. 4), or Hanks's saline supplemented with human and/or calf serum, antibiotics, various other additives, all media being buffered with bicarbonate (pH 7.2) against 5 per cent carbon dioxide in air. Samples of the oocytes were examined as whole mounts stained with aceto-orcein at various intervals after liberation in order to record the presence of a germinal vesicle or the stage of meiosis. The culture techniques were designed to encourage the migration of the corona and cumulus cells from the oocytes on to the 'Falcon' plastic used for culture, for these cells make microscopy difficult and are difficult to remove enzymatically. In almost all species examined a low proportion of the oocytes possessed a polar body and were at metaphase of the second meiotic division (metaphase-II) or were pycnotic when recovered; these oocytes were usually devoid of granulosa cells and were presumably atretic⁴.

Mouse. With Difco Medium 199 supplemented with 15 per cent serum, 80 per cent of the oocytes resumed meiosis (Table 1), which is in good agreement with earlier estimates⁵. The hormonal state of the mother had no detectable effect on the proportion of oocytes resuming their maturation. A high pH in the medium, prolonged exposure to heparin, or high concentration of antibiotics (1,000 i.u./ml.) reduced the proportions maturing, often to nil. Almost all maturing oocytes reached early anaphase of the first meiotic division (anaphase-I), their rate of maturation to this stage being similar to the rate found

in vivo after injecting LH into the mother⁶. Some oocytes became blocked in their maturation at early anaphase-I (Fig. 1), while the remainder progressed normally to metaphase-II and extrusion of the first polar body (Table 1). The block at early anaphase-I will be discussed below.

Table 1. MATURATION OF MOUSE OOCYTES IN DIFCO MEDIUM 199 WITH 15 PER CENT BOVINE SERUM AND 100 I.U. PENICILLIN/ml.

Duration of culture (h)	Germinal vesicle (dietyate)	Developmental stage of oocyte			
		Meta-phase-I	Early ana-phase-I	Late ana-phase-I or telophase-I	Metaphase-II and first polar body
0	76	1	—	—	3*
8.5	8	7	11	—	1
10	9	5	15	6	1
12.5-13	8	—	3	—	27
15	16	—	16	—	31
18	4	—	3	—	9

* These oocytes were presumably atretic.

After priming mice with follicle-stimulating hormone preparations followed by LH-preparations, oocytes are in anaphase between 8 and 11 h after the injection of LH, polar body extrusion begins at 10 h and is virtually complete in all oocytes by 12 h after the LH injection (ref. 6).

Cow. Ovaries were obtained from two cows in the luteal and one in the follicular stage of the cycle. Nine of the oocytes were examined immediately, and each possessed a germinal vesicle. The remaining 14 oocytes were cultured and all had a polar body and were in metaphase-II when examined 31 h later. Ovulation occurs 24-36 h after injecting LH into cows⁷.

Sheep. Ovaries were obtained from two sheep in their follicular phase. Ten oocytes examined immediately possessed a germinal vesicle. Six oocytes examined after 22.5 h in culture were in metaphase-I, and out of seven examined after 46 h four had a polar body and were in metaphase-II. Polar body extrusion *in vivo* requires less than 40 h after an injection of LH into the mother⁸.

Pig. I am indebted to Dr. C. Polge for permission to quote these results of our joint work. In this species, a delay of 20-24 h occurs between the injection of LH into the mother and the breakdown of the germinal vesicle⁹. A similar delay *in vitro* after liberation of the oocytes would help to explain our earlier results where germinal vesicles persisted for 20 h in cultured human and primate oocytes. Pigs were killed on day 12 of their cycle, that is, when corpora lutea were still active and the numbers of Graafian follicles maximal, or on day 18, when the corpora lutea

Fig. 1. Mouse oocyte blocked in its maturation at early anaphase-I. The spindle is formed and the chromosomes are extended along it. Whole mount stained in aceto-orcein. ($\times 1,500$)

Fig. 2. Metaphase-II and first polar body (slightly out of focus in lower part of figure) in a cultured pig oocyte. Whole mount stained in aceto-orcein. ($\times 675$)

Fig. 3. Group of metaphase-II chromosomes in a human egg. Slight pressure applied after staining has brought many of the chromosomes into focus but has destroyed the outlines of the spindle. Whole mount stained in aceto-orcein. ($\times 600$)

had regressed and the wave of atresia had passed. In culture there was a delay of 20–24 h before breakdown of the germinal vesicle, and meiosis was then resumed (Table 2). Most oocytes had polar bodies, and were in metaphase-II after 43 h in culture (Fig. 2), although some were blocked at early anaphase-I. The rate of maturation was similar in oocytes from pigs killed on the 12th or 18th day of the cycle, and was closely comparable with that occurring *in vivo* during the natural cycle or after injecting LH into the mother⁹.

Rhesus monkey. Ovaries from 4 monkeys were available. Polar body extrusion required approximately 30 (Table 2). Several oocytes displayed blocking at anaphase I, especially if grown in Burroughs Wellcome Medium 199. Ovulation occurs 24–48 h after the injection of LH in female monkeys¹⁰.

Man. Only small pieces of ovary from patients undergoing surgery for various disorders were available, and the number of oocytes from any one piece were seldom sufficient to provide samples for examination after different periods of culture. All oocytes from one Steir Levant patient failed to mature *in vitro* and have been excluded from Table 2. This might have been an example of the endocrinological state of the mother influencing the maturation of oocytes *in vitro*. Several oocytes examined after 24 h had prometaphase chromosomes. Polar body extrusion evidently required a maximum of 40–48 h (Table 2, Fig. 3). Ovulation occurs 24–48 h after the injection of LH into women¹¹.

Block in Development at Early Anaphase-I

The block at anaphase-I might have physiological significance, for a natural arrest of development occurs in most mammalian species at late metaphase-II just before fertilization. With Difco medium 199 supplied ready for use, between 10 and 45 per cent of mouse oocytes were blocked in replicate cultures (Table 1), whereas with Burroughs Wellcome 10 times concentrated 199 approximately 80 per cent were blocked, the great majority at early anaphase-I and a few at telophase (Table 3). In many blocked oocytes a distinct bulge from the vitellus could be seen next to the spindle after fixation. Maturation was blocked rather than delayed, for prolonging the culture period did not alter the incidence of blocked oocytes (Tables 1 and 3). Examination of the listed contents of the two media 199 revealed no differences in composition to explain why one should cause more blocking than the other, the major difference being the inclusion of Earle's saline in Burroughs Wellcome 199 as opposed to Hanks's saline in Difco 199.

Nevertheless, blocking was evidently due to deficiencies in the culture medium as shown by the following experiments. First, a sample of mouse oocytes was divided into three groups and cultured in Difco 199, Burroughs Wellcome 199, or a mixture of equal parts of the two. The incidence of blocking was profoundly influenced by

100 199+15 per cent bovine serum	—	14	5

* 100 i.u. penicillin added to all media.

† HCG, human chorionic gonadotrophin.

the culture medium (Table 4). Secondly, mice were super-ovulated with gonadotrophins⁶, and 2 h after the injection of HCG their oocytes were liberated. Polar body extrusion from these oocytes would have occurred *in vivo* within 9 h. After 15 h in Difco 199 and 15 per cent calf serum, 7 of the 19 oocytes were blocked. Thirdly, even the use of neat or diluted pig follicular fluid failed to alleviate the block in mouse oocytes (Table 4).

Various attempts, so far unsuccessful, have been made to alleviate the block at anaphase-I by modifying the culture medium. Blocking could not be attributed to epiparin, the source of serum or distilled water, the pH of the medium (although higher pHs reduced the proportion slightly), or to the antibiotics in the medium. Nor was the incidence of blocked oocytes influenced by the provision of feeder cells (*L*-strain or granulosa monolayers), addition of extra ATP, addition of extra oxidized and/or reduced glutathione in case extra disulphide or sulphhydryl groups were required by the oocytes for anaphase separation¹², addition of folic acid and ascorbic acids to facilitate the shedding of RNA attached to chromosomes at metaphase¹³, or changing the gas phase to 5 per cent carbon dioxide in oxygen. Fertilized 1-celled mouse eggs are difficult to grow *in vitro* and the block at early anaphase might be due to similar deficiencies in the culture medium.

Experimental Studies with Oocytes maturing *in vitro*

Oocytes maturing *in vitro* are evidently not atretic. This is shown by: (1) the similarity in all species examined between the duration of maturation *in vitro* and *in vivo*; (2) the profound influence of the culture medium on the incidence of blocking an early anaphase-I; and (3) observations that matured rabbit¹ and pig¹⁴ oocytes can be fertilized *in vivo* and that the fertilization of matured human oocytes can proceed *in vitro* at least as far as penetration of spermatozoa into the perivitelline space¹⁵. The technique thus promises to provide excellent material for investigating the dynamics of early mammalian development. For example, the role of the centrioles in

meiosis and fertilization could be investigated using the techniques applied to the sea-urchin egg¹⁶; the spindle of the second maturation division is formed within 30 min of the previous telophase which implies a rapid re-organization of the centrioles. Distinct asters with astral fibres attached to the nearest point on the egg membrane could be seen in several mouse oocytes at the first and second meiotic division, and this eccentric attachment of the fibres to the membrane could account for spindle rotation at telophase and the smallness of the polar bodies. Chromosome mechanics at meiosis could also be examined, especially with reference to meiotic anomalies leading to trisomy in oocytes from older women².

The technique also offers the opportunity of investigating early development in species difficult to study otherwise, for example, primates, and of obtaining many oocytes and increased numbers of progeny from valuable livestock by egg transfer. Large numbers of oocytes can be handled in culture: we have handled up to 700 pig oocytes on several collections without undue difficulty¹⁴. With these numbers it should be possible to apply biochemical analyses to mammalian eggs similar to those applied to invertebrate and amphibian eggs. Ribosomal RNA is synthesized during the pre-ovulatory and pre-neurula stages in amphibians, sRNA and mRNA synthesis increasing considerably during late cleavage¹⁷. A similar situation might hold in mammals, where increasing amounts of RNA are synthesized after the second cleavage¹⁸. Several phenomena occurring in the mammalian morula might be related to the initiation of mRNA synthesis at this stage, for example, the initiation of heterochromatin in the sex chromosomes and sex chromatin in the nucleus¹⁹.

I thank Miss C. Jackson for her assistance.

PROCESSES OF EXCITATION AND INHIBITION IN SINGLE MECHANORECEPTORS (PACINIAN CORPUSCLES)

By DR. O. B. ILYINSKY

I. P. Pavlov Institute of Physiology, U.S.S.R. Academy of Sciences, Leningrad

INVESTIGATING various properties of Pacinian corpuscles we found that in a number of cases their electrical response contains positive deviations of potential, the origin of which is impossible to understand within the limits of present concepts of their activity¹⁻⁴. Some peculiarities of this phenomenon are discussed in the

present article. A detailed description of the experimental technique has been presented elsewhere⁵⁻⁸.

Fig. 1 demonstrates gradual reaction of the receptor elicited by mechanical shocks of triangular form. It is seen that with increase in duration of the stimulus the response declined in amplitude, decreased in rate of rise

and increased in duration. In some records²⁻⁵ a little hyperpolarization of gradual character appears. It may be noticed also that the appearance of depolarization is associated only with the effect of the posterior front of the stimulus. Its anterior front either produces no changes or gives rise to positive deviations of the potential. The diminution in the amplitude and in the rate of rise of the gradual response of the receptor with the decrease of the velocity of displacement has already been described⁹.

It is well known¹⁰ that the capsule of the receptor, while strongly attenuating the static component of the stimulus, conducts its dynamic component well. The prolongation of the triangular stimulus is actually equal to the increase in duration of the dynamic component of such stimulation. Therefore the observed increase in the duration of the gradual response means that the receiving elements of the mechano-sensitive membrane of the Pacinian corpuscles adapt themselves to the long-lasting stimulus much more slowly than was previously thought (see also refs. 11 and 12). The fact that the reactions of the receptor to the ascending and descending parts of the mechanical shock differ is more difficult to understand, for it is well known^{5,8,9} that responses of the intact corpuscles to the on- and off-stimuli are more or less identical. Furthermore, it is now clear⁸ that mechanical shock produces oscillations in the capsule of the receptor which, provided the stimulation is sufficiently long, induce off-reaction, that is, the mechanism of generation of off-responses is actually the same as that of on-responses. If the amplitude of mechanical stimulus is sufficiently large these oscillations evoke multiple responses of the receptor (see also Fig. 2, 11).

The systematic study of a great number of receptors showed that, in practice, depolarization of the nerve ending is always accompanied by hyperpolarization phenomena and not infrequently the reactions to anterior and posterior fronts of the stimulation may be essentially different especially when long-lasting triangular (sinusoidal) mechani-

Fig. 2. Response of the receptor under different conditions of stimulation (11 different Pacinian corpuscles). In 6b, amplification in the system of recording the mechanical shock (lower beam) is diminished in relation to 6a and the direction of the shock is changed. In 7b, the receptor is killed and the absence of mechanical artefact in the system of recording under stimulation greater than in 7a is demonstrated. In 8b the direction of shock is changed as compared to 8a. Peak potentials in 8b, 9, 10 are blocked by procaine. The appearance of depolarization responses in almost all records in switching off the stimulation is evidently connected with the origin of oscillation process in the capsule of the receptor (see record 11); time mark: 1, 3, 5-0 msec; 2, 5, 8, 10, 11, 4-0 msec; 4, 3-0 msec; 6, 7, 9, 2-0 msec; calibration: 1, 3, 4, 5, 6, 7, 8, 11, 20-0 μ V; 2, 30-0 μ V; 9, 10, 15-0 μ V.

cal shocks are applied. Records presented in Fig. 2 illustrate the phenomena in question. It can be seen that the amplitude, rate of rise, duration and shape of the positive response of the receptor vary both from experiment to experiment and in the same experiment. The appearance of hyperpolarization is in no way connected with the moment of the spike origination and is observed even in its absence. However, positive deviations of the potential are most clearly observed on the background of the preceding depolarization. The character of the reaction is to a great extent determined by the amplitude and duration of the mechanical shock as well as by the site of its application, etc.

It is known¹³ that the nerve ending in the Pacinian corpuscle has the shape of an elliptic cylinder. Hubbard¹⁴ suggested that the ratio between the great (*a*) and small (*b*) transverse axes of the nerve ending is increased by stimulation. Consequently the surface of the receptor membrane increases, which results in excitation.

However, the increase in the ratio *a* : *b* occurs only if the mechanical stimulus is applied along the axis 'b'. The stimulus directed along the axis 'a' decreases the ratio *a* : *b* and consequently decreases the surface of the receptor membrane. Suppose that depolarization of the nerve ending membrane is caused by an increase (distension) and hyperpolarization by a decrease (constriction) in the surface of the latter. Then stimulation applied along the axis 'b' would produce depolarization, while that falling in the direction of the axis 'a' would evoke hyperpolarization. In experimental verification of this assumption possible appearance of oscillation processes in the capsule of the receptor had to be taken into consideration⁶. In this connexion short-lasting shocks with considerable amplitude and rate of rise were not to be used, as the phenomena of hyperpolarization would have been masked by arising depolarizing responses.

In Fig. 3 are shown oscillograms which demonstrate a good agreement between expected and experimental data. It is obvious that with rotation of the corpuscle around its longitudinal axis the anterior front of the long-

Fig. 3. Changes in the response of mechanoreceptor (lower beam) caused by alterations in duration of mechanical stimulation (upper beam). Peak potentials are blocked by procaine. Calibration 50-0 μ V; time mark (msec): 1-7, 5-0; 8, 10-0.

Fig. 3. Functional asymmetry of the receptor. Top: scheme of supposed correlation between the direction of stimulus and position of the nerve ending (its small transverse axis). Bottom: corresponding schemes of responses of Pacinian corpuscles in two different experiments. In 2 spikes blocked by procaine; time mark (msec): 1 and 2, 4.0; calibration (μ V): 1, 10.0; 2, 5.0

sting stimulus which is responsible for depolarizing action produces hyperpolarization response and vice versa. It should be noted that reverse-directed deformation due to elastic properties of the capsule at the moment of cessation of stimulation arises⁸ and therefore the

posterior front of the stimulus acts contrary to the anterior one.

On the basis of the data obtained, the responses of Pacinian corpuscles presented in Figs. 1 and 2 may be readily explained (a detailed consideration of the hyperpolarization phenomenon will be presented elsewhere). Positive deviations of potentials are usually accompanied by some decrease in the receptor excitability (Fig. 2, cf. 2a and 2b); therefore, on the analogy with inhibitory synaptic potentials, they may be referred to as inhibitory receptor potentials (IRP), while the negative changes in the potential may be called excitatory receptor potentials (ERP).

In view of the data obtained the participation of mediators in the processes of excitation of Pacinian corpuscles¹⁴ seems scarcely feasible.

A NEW FLUORESCENT ANTIBODY METHOD: MIXED ANTIGLOBULIN IMMUNOFLUORESCENCE OR LABELLED ANTIGEN INDIRECT IMMUNOFLUORESCENCE STAINING

By PROF. E. H. BEUTNER*, DR. E. J. HOLBOROW and G. D. JOHNSON

Medical Research Council Rheumatism Research Unit, Canadian Red Cross Memorial Hospital, Taplow, Maidenhead, Berkshire

INVESTIGATIONS by Coombs *et al.* on mixed agglutination¹ and mixed antiglobulin tests² have revealed that an antibody combined with its specific antigen on a cell may have a free antibody combining site capable of reacting with another molecule of its specific antigen. In the mixed agglutination tests these free combining sites are detected with antigens (immunoglobulins for the mixed antiglobulin tests) attached to red cell indicators. We have investigated the use of antigens (immunoglobulins) labelled with fluorescein^{3,4} in a similar system using frozen tissue sections⁵ as primary antigens. This method may be referred to as mixed antiglobulin immunofluorescence (IF) or mixed immunofluorescence (MIF). Unfortunately the latter term may be confused with the 'mixture of colours'⁶ obtained by labelling with different fluorochromes, so that the cumbersome but more accurate term 'labelled antigen indirect IF staining' may be preferable to describe the method. For the sake of clarity the established IIF (indirect immunofluorescent) staining procedure⁶ may now be referred to as the 'labelled antiglobulin indirect IF staining' in contradistinction to the 'labelled antigen indirect IF' or MIF method.

Fig. 1 provides a diagrammatic comparison of the principles involved in labelled antiglobulin and labelled antigen indirect IF staining. Table 1 summarizes the specific techniques employed in the labelled antigen or MIF staining method.

Serial dilutions of human sera containing tissue antibodies were tested on frozen sections of tissue cut in a cryostat⁷. Labelled immunoglobulins were prepared by

conjugating either commercial human serum fraction FII or IgG prepared by DEAE chromatography. For conjugation, 0.08 mg FITC/mg protein was found to yield satisfactory reagents (FITC, fluorescein isothiocyanate, was obtained from Nutritional Biochemicals Corporation, Cleveland, Ohio). Both the antiglobulin (step 3) and the normal rabbit serum used as the diluent (after 1:15 dilution in buffered saline) of the labelled antigen (step 5) were heat-inactivated before dilution because some slight enhancement of MIF staining (sometimes as much as a whole dilution in the staining end-point of the human serum) could be effected thereby.

The precipitating activity of the antiglobulins and of the labelled antigens provided estimates of their respective antibody and antigen activities. A concentration of 1 unit/ml. of antiglobulin was defined as the highest dilution which would give a visible line of precipitation in a standard agar-gel diffusion precipitation test (6 wells 8 mm from a centre well, all 2.5 mm in diameter) using serial 2-fold dilutions of the antiglobulin in the peripheral wells and 1 mg/ml. of IgG or FII in the centre well. Conversely, 1 unit/ml. of labelled immunoglobulin was

Table 1. PROCEDURE FOR MIXED ANTIGLOBULIN OR LABELLED ANTIGEN INDIRECT IF

Step	Reagents	Conditions	Time (min)
1	Human sera	Serial dilutions to end-point	20
2	Wash	PO ₄ buffered saline	60
3	Anti-human immunoglobulin	Heated 56° C 30 min, diluted to 1-4 units	20
4	Wash	PO ₄ buffered saline	60
5	Labelled human immunoglobulin	Diluted to 1-2 units in heated normal rabbit serum (1/15 dilution)	20
6	Wash	PO ₄ buffered saline	120
7	Glycerin mount	1/10 buffer: 9/10 glycerin	

* Permanent address: State University of New York at Buffalo, Schools of Medicine and Dentistry, Buffalo, New York.

defined as the concentration present in the highest dilution yielding a visible line of precipitation with 2 units of an antiglobulin in the centre well. Most labelled preparations of *IgG* or *FII* which we have used have contained about 0.05 mg of protein/ml. in 1 unit. A more detailed report on the relation between the unitages of antiglobulins and labelled immunoglobulins and their respective reactivity in MIF staining will be made at a later date¹⁴.

Phosphate-buffered saline⁸ served as a diluent for all reagents as well as a washing solution. Prolonged washing (60 min for steps 2 and 4 and 120 min for step 6 in Table 1) was used to minimize non-specific staining. While some exploratory studies indicated that washing times of 20, 20 and 120 min (for steps 2, 4 and 6, respectively) might yield equally satisfactory results, the prolonged washing times listed in Table 1 were adhered to throughout most of these investigations to provide an added margin of safety. Fluorescence microscopy was performed as described previously⁷.

Studies of MIF or labelled antigen IF staining revealed that under the conditions used non-specific staining ranged from an undetectable to a low acceptable level. The latter appeared as a dull-green background staining which could readily be distinguished from specific IF staining. In most of these investigations it was difficult to distinguish between some traces of green auto-fluorescence of tissue and traces of non-specific staining.

The appearance of specific MIF staining patterns given by tissue antibodies, such as antinuclear factor* (ANF), could not be distinguished qualitatively (in readings of coded preparations) from those obtained in parallel studies by the established labelled antiglobulin indirect IF staining procedure. At the quantitative level, comparisons were made by titrating human sera (usually in doubling dilutions) to IF staining end-points. An end-point was defined as the highest dilution of the patient's serum which yielded an IF staining reaction clearly distinguishable from that of negative control sera. Preparations were randomized and read as unknowns by two or more observers. Under these conditions, IF staining end-points varied by as much as plus or minus one doubling dilution.

Table 2. TITRATIONS OF ANTINUCLEAR AND ANTINUCLEOLAR ANTIBODY BY THE LABELLED ANTIGEN (MIF)* AND LABELLED ANTIGLOBULIN (IIF) INDIRECT IF* STAINING METHODS

Case	Sera tested Type of antibody	Dil. of sera	IF staining reactions			
			Rabbit anti-human		Goat anti-human	
			MIF	IIF	MIF	IIF
B	None	1:25	-	-	-	-
		1:100	+	+	+	+
		1:200	+	+	+	+
		1:400	+	+	+	+
		1:800	W*	W	W	W
		1:1,600	W	-	-	W
W	Nucleoli	1:25	+	+	-	+
		1:50	W	W	-	W

* IF, immunofluorescence. MIF, mixed (antiglobulin) IF or labelled antigen indirect IF. IIF, indirect IF or labelled antiglobulin IIF.

Rabbit and goat anti-human antisera to human *IgG*. Other antibodies could be demonstrated in these by immunoelectrophoresis but did not appear to be relevant to the MIF or the IIF staining reactions as judged by comparison with monospecific antisera to *IgG*.

ANF, antinuclear factor.

+, moderate to strong positive.

W, weak positive.

Table 2 summarizes some typical titrations performed with human sera containing two types of antibodies. Titrations were performed by the labelled antigen and labelled antiglobulin methods using both goat and rabbit antisera to human immunoglobulins. For both the MIF and IIF staining 4 units of the goat antiserum were used while the rabbit antiserum was used at dilutions containing 2 units and 1/5 units for the MIF and IIF staining respectively. Both antiglobulins contained not only antibodies to human *IgG* (as indicated by their unitage) but also antibodies to other serum proteins as revealed by immunoelectrophoresis. For MIF staining 2 units of labelled human immunoglobulin (*FII*, Koch Light Laboratories, Ltd., Colnbrook, Buckinghamshire) with an estimated molar fluorescein to protein ratio of 8.1/1 was used as antigen for the top layer.

The serum of patient *D*, as shown in Table 2, yielded nuclear staining titre of 1:800 or 1:1,600 by both the MIF and the IIF staining methods under the conditions used. Essentially comparable results were obtained with the goat and rabbit antiglobulins. Similarly, the serum of patient *W*, which contained antibodies to nucleoli

Fig. 1

Fig. 2

ielded comparable reactions by the MIF and IIF staining methods with the rabbit antiglobulin. However, the cat antiglobulin only yielded a detectable reaction by IF, not by the MIF staining method. This is the most iscrepant result in this series of experiments; it is doubtful if much significance can be attached to it because the difference is close to the limits of error of the method ± 1 dilution).

Several types of tissue antibodies (probably all autoantibodies) were tested by both the MIF and IIF staining methods. The results of these studies are summarized in Table 3.

Table 3. EXAMPLES OF TITRES OBTAINED WITH SOME HUMAN ANTIBODIES TO TISSUE ANTIGENS BY THE LABELLED ANTIGEN (MIF)* AND LABELLED ANTIGLOBULIN (IIF)* INDIRECT IF* STAINING METHODS

Systems tested	Literature ref.	Tissues	Examples of titres	
Type of antibody			By MIF	By IIF
Antinuclear factor	8, 9, 17			
Smooth		Calf thyroid	1:200	1:200
Speckled		Calf thyroid	1:200	1:400
Nucleolar		Calf thyroid	1:50	1:50
Thyroid microsomal	10	Human thyroid	1:100	1:100
Muscle striations	11, 12	Human heart	1:100	1:200
Skin antibodies:				
Intercellular	13	Guinea-pig lip	1:30	1:90
Basement zone	13	Guinea-pig lip	1:270†	1:270†
Cytoplasmic	14	Guinea-pig lip	1:30	1:30

* Abbreviations as for Table 2.

† No end-points were obtained in these particular titrations.

Antinuclear factors^{8,9,17} of various sorts could be demonstrated by both MIF and IIF staining as shown in Table 3. Identical staining patterns were seen in preparations stained by the two methods. IF staining of thyroid cells¹⁰ yielded strongly positive reactions by the labelled antigen method. Preliminary studies of muscle autoantibodies found in sera of patients with myasthenia gravis^{11,12} yielded comparable reactions by the two IF staining methods. Three types of skin antibodies^{13,14} could be demonstrated by MIF staining as well as IIF staining.

The prime objective of these investigations on labelled antigen indirect IF staining was to seek a better understanding of the quantitative relationships that obtain in the conventional labelled antiglobulin method. The approach used in these investigations was that of chess-board titrations. Fig. 2 illustrates the results obtained in one experiment of this type. An antiglobulin monospecific for IgG was tested at varying dilution against doubling dilutions of an ANF. The precipitation end-point of this antiglobulin (1 unit per ml.) was 1:32. The labelled IgG antigen used for the top layer has an estimated $F:P$ ratio of 3.6/1 and was used at a concentration of 1 unit/ml. (0.05 mg protein/ml.).

The results summarized in Fig. 2 reveal that the ANF titre maintains a plateau (in the range of 1:200–1:400) down to an antiglobulin dilution of 1:32 (1 unit/ml.). At higher dilutions of the antiglobulin the ANF titre declines, falling off to a negative reaction at $\frac{1}{8}$ of a unit per ml.

These observations provide a basis for making the following assumptions in quantitative studies of indirect IF staining (both IIF and MIF). (1) Titration of a standard human serum yields a constant IF end-point (± 1

dilution) over a range of antiglobulin dilutions, forming a plateau in a chess-board titration as in Fig. 2. The highest antiglobulin dilution in this plateau yielding the maximal titre (± 1 dilution) of IF staining for a given human serum is the antiglobulin plateau end-point. (2) The antiglobulin plateau end-point is roughly proportional to the precipitation end-point of the antiglobulin. (3) Non-specific staining is proportional to the fluorescein concentration in the conjugate dilution used for IF staining. (4) The titre of IF staining obtained with a given human serum is proportional to the $F:P$ ratio of the labelled antiglobulin (in IIF) or labelled antigen (MIF). It must be added that over-conjugation, that is, too high a fluorescein to protein ($F:P$) ratio, so alters the protein that it gives rise to unacceptable non-specific staining¹⁵. (5) In labelled antigen indirect IF staining the maximal titre obtained with a given human serum is maintained over a range of dilutions of the labelled antigen of the top layer, again in a plateau fashion. The highest antigen dilution in this plateau which yields maximal titres is the labelled antigen plateau end-point. This labelled antigen end-point is also roughly proportional to its precipitation end-point.

More recent studies^{12,16} have revealed that essentially these assumptions hold true for either MIF staining or IIF staining.

From the foregoing it appears that the control of the following is required for quantifying indirect immunofluorescence: (1) Characterization of antiglobulins by immunoelectrophoresis (2) Titration of antiglobulins by precipitation tests (for MIF staining the labelled antigen must also be titrated). (3) Estimation of the fluorescein concentrations and fluorescein to protein ratios in conjugates. These parameters are minimal requirements for quantitative indirect immunofluorescence.

EFFECT OF A LIPID FRACTION FROM RAT THYMUS ON DELAYED HYPERSENSITIVITY REACTIONS OF NEONATALLY THYMECTOMIZED RATS

By PROF. BRANISLAV D. JANKOVIĆ, DR. KATARINA ISAKOVIĆ and JOZEF HORVAT

Microbiological Institute, Faculty of Pharmacy, and Immunology Unit, Institute of Biology, University of Belgrade, Yugoslavia

IT is now clear that the thymus has an important role in the development of immunological capacity in mammals¹. Neonatal thymectomy is followed by a striking depletion of lymphocyte population in various lymphoid tissues². The immunological role of the thymus has been considered by many investigators to be in the main indirect, this organ providing the body with cells which colonize different lymphoid tissues where they undergo further immunological maturation. Such a cellular function of the thymus does not, *a priori*, exclude the possibility that the thymus may have endocrine activity³ and that the development of the immune system may be influenced by active principles elaborated by the thymus and discharged into the circulation⁴. Interest in this possibility has been revived recently by Szent-Györgyi *et al.*⁵, who isolated two substances from thymus, among other organs, capable of affecting tumour growth. The observations presented here form part of a large experiment in which various fractions of rat thymus have been used in attempts to restore immunological potential to rats thymectomized at birth.

Thymuses from 18–28-day-old outbred albino rats were used as source for the preparation of lipid fraction: 12 g tissue was homogenized with 150 ml. of saline, followed by lyophilization of homogenate. Dried tissue was extracted with chloroform-methanol (2:1 by volume) at boiling-point for 12 h. The lipid fraction from whole rat central nervous tissue was prepared in a similar way. Lipid fractions were emulsified separately in saline before injection. Inbred Lewis strain rats (Microbiological Associates, Washington) were used in the experiment. Thymectomy was performed at birth, and operated animals were divided into three groups. The first group was treated with the thymus lipid fraction; the second group with the central nervous tissue lipid, and the third group was not treated. Two control groups of normal rats were also included. One control group (sham-operated) was treated with the central nervous tissue lipid, whereas another group (unoperated rats) was untreated. Each treated thymectomized or sham-operated rat received a total of 11 injections, beginning at 21 days and ending at 58 days of age. The individual inoculations contained 2.6 mg of thymus or nervous tissue lipid extract. Thymectomized animals showing the wasting syndrome were excluded from the experiment.

At 8 weeks all rats were immunized with crystallized bovine serum albumin dissolved in saline and mixed with an equal volume of complete Freund's adjuvant. 0.1 ml. of a stable water-in-oil emulsion (0.8 mg of bovine serum albumin) was injected into the left hind foot-pad. The first skin test was done 10 days, and the second 18 days, after immunization. 40 µg of bovine serum albumin in 0.1 ml. saline were injected into the skin of either left or

right depilated flank. Differential leucocyte counts were performed on tail blood taken 2 days after the first skin test. At 11 weeks all animals were killed and the mediastinum was inspected grossly and histologically for the presence of thymic remnants. Axillary lymph nodes and spleen were taken for histological appraisal.

Immunological responses of thymectomized and control rats, untreated or treated with the cell-free fraction of allogeneic thymus, are given in Table 1. Delayed reaction to bovine serum albumin were sharply reduced in untreated thymectomized rats. In contrast are the delayed hypersensitive responses of thymectomized animals treated with thymic lipid. At the time of the second skin test delayed reactivity in those rats was comparable to that of non-thymectomized controls. The responses of thymectomized rats treated with central nervous tissue lipid (CNS lipid) fell between those of untreated thymectomized rats and those of thymectomized rats repeatedly injected with thymic lipid.

Untreated thymectomized rats showed a moderate retardation in weight gain, a low incidence of wasting disease and a marked reduction in circulating lymphocytes (Table 2). The body-weight of thymectomized rats injected with thymic lipid, on the other hand, was comparable to that of sham-operated and intact controls. No wasting disease was seen in this group, and there was a partial restoration of total number of lymphocytes in the peripheral blood. Histological examination of spleen and lymph nodes from thymectomized rats, untreated or treated with central nervous tissue lipid, revealed a profound depletion of small lymphocytes, whereas the plasma cell population was found to be normal². The absence of small lymphocytes was less striking in the spleen of thymectomized animals treated with thymic lipid, and in the lymph nodes masses of these cells were larger than in other thymus-free rats which were not injected with thymic lipid. There were many foci of cellular proliferation in the cortical areas of those lymph nodes. These histological findings fit fairly well with the immunological responses of thymectomized animals treated with thymus lipid fraction.

None of several thymic materials used by other authors⁶ has been effective in preventing wasting disease or in

toring immunological competence to thymectomized ce. It has been claimed, however, that injection of thymus extracts into animals produces a temporary rease in lymphocyte number⁷. The results presented re suggest that the thymus is capable of elaborating ive principles which influence immunological reactivity thymectomized rats in terms of restoring their immune tential. One could assume that the humoral activity the thymus, as described in this experiment, might be iliar to the activity exerted by the tumour growth-omoting substance isolated by Szent-Györgyi *et al.*⁵. should be mentioned, however, that Dalmasso *et al.*⁶ led to restore immunological potential to neonatally ymectomized animals by repeated injections of 'pro-ne'. The reported humoral activity of the thymus ems to be related to thymic lipid, lipoprotein or lipoluble components. Several injections of highly polymered deoxyribonucleic acid isolated from young rat ymus increased, to some extent, the delayed hypernsitivity response in rats thymectomized at birth (unpublished results). Thus the immunological reactivity tained was quantitatively similar to that of rats treated ith central nervous tissue lipid, but it never reached the vel of delayed reactions observed in thymectomized rats jected with thymus lipid fraction.

Thymus lipid(s) exerted restorative effects on lymphocytes in the circulation and lymphoid tissues. This ovides the histological substrate to the corrected munological inadequacy, but does not itself explain e re-population of lymphoid cells, that is, whether umoral thymic factor(s) act solely by stimulating

mesenchymal cells of lymphoid tissues, or through the mechanism of immune recognition. Although the present results do not offer evidence as to the thymus cells to which humoral function could be attributed, it might be assumed that this activity is related to the central cellular architecture of this organ. The implied humoral role of the thymus, however, is not inconsistent with the possibility that the thymus acts as the source of cells involved in delayed hypersensitivity responses.

PRECIPITIN ACTIVITY IN THE SERA OF PATIENTS WITH DEFICIENCY OF β -LIPOPROTEINS (ACANTHOCYTOSIS)

By DR. R. F. MURRAY, jun.

The National Institutes of Health, Bethesda, Maryland

AND

PROF. B. S. BLUMBERG*

Institute for Cancer Research, Philadelphia, Pennsylvania

WHILE searching for isoprecipitins in the sera of multiply-transfused patients¹, the sera from two patients with a deficiency of β -lipoproteins were tested by double diffusion in agar² against a panel of normal human sera. Weak but definite precipitin lines formed. The lines were stained by the specific lipid-stain, sudan black B (ref. 3). The studies reported here were undertaken to confirm this observation and to characterize the reaction further.

Sera which had been stored at -25° for approximately one year were available from the two original patients (M. S. and A. C.), and fresh specimens were obtained from two additional patients (L. Z. and N. S.) with the same disease. The precipitin reaction was detected in all of these, with the exception of a second specimen from M. S. Serum from N. S. showed the strongest reaction of the four specimens tested. The best results were obtained when reactant proportions of two (N. S. serum) to one (normal serum) were used. Precipitin lines that developed within 16 h and stained with sudan black B were observed between N. S. and 29 of 30 sera from American white individuals. Under similar conditions sera from L. Z. and A. C. gave weaker and less-well-defined reactions. The low-density lipoproteins (specific gravity < 1.063) from 36 individuals were isolated by flotation in a salt medium of specific gravity 1.063 by the method of Havel *et al.*⁴. Thirty-five of these 36 isolated lipoprotein specimens

reacted with serum from L. Z., A. C. and N. S. (Fig. 1). The isolated lipoproteins failed to react with any of ten-fold concentrated sera from ten normal, white individuals. The > 1.063 fraction of the fractionated sera did not produce a precipitin reaction even when concentrated by ultrafiltration to a degree comparable to that of the low-density lipoprotein fraction (ten-fold concentrated).

In order to characterize the precipitin in the sera of the acanthocytosis patients, the immunoelectrophoretic method of Grabar and Williams⁵ was modified as follows. Sera from A. C. and L. Z. were concentrated three-fold by ultrafiltration, placed in the centre well, and subjected to electrophoresis in 1 per cent agar in veronal buffer, pH 8.6, ionic strength 0.05, for 1 h at 6 V/cm. Isolated low-density β -lipoprotein was placed in one trough and whole serum in the other. A single arc developed when the whole serum was used, and two arcs formed opposite the isolated low-density β -lipoprotein. The arc common to both troughs was broad, with indistinct borders. It had a cathodal mobility intermediate to that of β - and γ -globulins. The second arc had an anodal migration which corresponded to that of albumin or an α_1 -globulin, and was about one-half as intense as the slower arc. Both arcs tended to form very near the trough, and neither alteration of the concentration of reactants nor moving the trough farther from the well influenced their position significantly (Fig. 1). The clearest arcs were noted when isolated lipoprotein diluted 1:3 with saline was used.

* Present address: Division of Medical Genetics, Department of Medicine, University of Washington School of Medicine, Seattle.

Specific goat anti-human immunoglobulin antisera obtained from Dr. W. Terry, National Institutes of Health, were used in an attempt to relate the precipitin activity in the acanthocytosis serum to that of three of the known immunoglobulins (γA , γM and γG)⁶. The position of the major component was similar to but not identical with that of the γA -immunoglobulin (Fig. 2). Serum from patient A. C. was absorbed in the test-tube and in agar gel with these three antisera, but the precipitin activity was not removed. Five ml. serum from patient A. C. was subjected to column chromatography on DEAE in phosphate buffer at pH 7.0. The serum was placed on a column 1 cm \times 25 cm and the protein fractions were eluted in a stepwise fashion using 0.005, 0.025 and 0.5 M phosphate buffers. The precipitin activity could not be demonstrated in any of the four fractions obtained despite five- to ten-fold concentration of each of the fractions.

Serum from patient A. C. was tested, using the Ouchterlony technique, against the isolated β -lipoprotein specimens from 24 normal individuals. This same panel was tested with the human anti- β -lipoprotein antiserum C. de B.⁷ Nineteen of the 24 specimens reacted with C. de B. while all 24 of the specimens reacted with serum from patient A. C. The precipitin reaction with A. C. occurred after 4 h, while that with C. de B. occurred after 16 h. Precipitin arcs with C. de B. formed approximately midway between the centre (antiserum) and peripheral (panel sera) wells, while that with patient A. C. formed immediately adjacent to the peripheral well. These observations suggest that the precipitins in the acanthocytosis sera are different from those developed in multiply-transfused patients. Other experiments were performed which showed that the precipitin band stains only weakly, if at all, with the protein stains, azo carmine and amido black 10B, but strongly with lipid stains. Repeated testing of a single normal serum specimen under the same experimental conditions usually, but not always, produced a precipitin line. The failure of precipitin band formation was not related to variations in pH, temperature, or buffer composition. The reaction did not fix complement using the technique of Sever⁸. The complex formed between the C. de B. antiserum and β -lipoprotein does not fix complement, but the reaction does conform to most other criteria for an antigen-antibody reaction⁹.

These findings and several recent reports in the literature suggest that the reaction observed is probably a non-specific precipitation reaction.

Fig. 1. The upper portion shows a representative Ouchterlony pattern. The centre well contains serum from a patient with deficiency of β -lipoproteins. Peripheral wells contain isolated low-density β -lipoproteins. The lower portion is an immunoelectrophoretic pattern of the serum from an acanthocytotic patient showing precipitin activity in the β_2 - γ -globulin and α_1 -globulin regions. Trough A contains horse anti-human antiserum. Trough B contains isolated low-density β -lipoproteins.

Fig. 2. Immunoelectrophoretic pattern of the serum of a patient with acanthocytosis, comparing the position of the precipitin region with that of known immunoglobulins. Wells contain the serum of patient A. C. Trough A contains goat anti- γM antiserum. Trough B contains isolated low-density β -lipoproteins. Trough C contains goat anti- γA antiserum.

Tomasi¹⁰ noted that certain extracts of human organ gave a non-specific precipitation reaction with normal human sera using a modified Ouchterlony technique². He presented evidence that albumin was the reactive component in the serum and that the tissue extract component migrated slightly toward the cathode or immunoelectrophoresis. Teichman and Vogt¹¹ also noted non-specific precipitation reactions occurring between the sera of patients with tuberculosis and old tuberculi obtained from an *H37Rv* strain of *M. tuberculosis*. They identified the serum component as an α_1 -lipoprotein by its immunoelectrophoretic mobility. The same serum component was also found in sera of normal individuals as well as in sera of patients with carcinoma of the lung. They further suggest that Tomasi's serum component as well as that of Peetom *et al.*¹² (who reported a precipitation reaction between normal human and certain animal sera and haemolysates of normal human red cells) are also α_1 -lipoprotein in nature. Other authors^{13,14} have reported non-specific precipitin reactions between tissue extracts and normal sera, but such a reaction has not been previously reported between two human sera or with the low-density β -lipoprotein of human sera. In addition, precipitin activity is found in two fractions of the acanthocytotic serum. It is possible, however, that the α_1 -globulin fraction contains antibody activity, since G. Strejan and I. Flechner were able to produce antibody with α_1 -globulin mobility in rabbits¹⁵.

In summary, the following findings support the hypothesis that the precipitin activity in the acanthocytosis patients is probably non-specific.

- (1) The precipitin arcs on immunoelectrophoresis have an atypical appearance compared with those seen using human, anti-human lipoprotein antisera such as C. de B.
- (2) Precipitin activity is noted in the albumin or α_1 -globulin region. Non-specific precipitin reactions, which have been previously described, also occurred in these regions.
- (3) The precipitin activity was not removed by absorption with three common anti-immunoglobulin antisera.
- (4) Precipitin activity has been demonstrated with nearly all the normal sera against which it has been tested.
- (5) Precipitin bands stain well with lipid stains but weakly, if at all, with protein stains.
- (6) It is unusual for antibody activity against the same antigen to develop in two classes of immunoglobulins in the same individual.
- (7) The complex formed does not fix complement.

Neither demonstration of a classical antigen-antibody precipitation curve nor localization of the precipitin activity in the β - or γ -globulin region on immunoelectrophoresis is sufficient evidence to classify the reactant in the acanthocytosis patient's serum as an antibody¹⁴. Niece and Barrett¹³ noted an atypical precipitin band when chymotrypsin was tested in agar against an anti-

arboxypeptidase antiserum produced in rabbits. The and was unlike that produced with carboxypeptidase A and stained with sudan black but not with bromphenol blue. The antiserum would neither agglutinate latex particles coated with chymotrypsin nor provoke passive cutaneous anaphylactic reactions in guinea-pigs with chymotrypsin as antigen. Both phenomena occurred when carboxypeptidase A was used as antigen. They concluded that the precipitin was spurious, probably resulting from precipitation in the agar of lipid released by enzymatic degradation of the lipoproteins in the antiserum. The precipitin bands noted in our experiments are similar to theirs and may also result from the action of an enzyme or enzymes in the serum of these patients with deficiency of β -lipoproteins.

A reaction between the low-density β -lipoproteins and two components in the serum of patients with deficiency of β -lipoproteins is clearly demonstrated for the first time. Further work is required to determine whether these components are peculiar to the sera of acanthocytotic patients and whether they are a result of, or play a part in production of, the deficiency of β -lipoprotein.

We thank Dr. Leonard Laster of the National Institute of Arthritis and Metabolic Diseases for giving us serum from patients L. Z. and A. C., and Dr. P. Ways of the University of Washington in Seattle for serum from patients M. S. and N. S.

DOUBLE CHROMOSOME REDUCTION IN A TETRAPLOID SOLANUM

By G. E. MARKS, DR. R. K. MCKEE and DR. J. B. HARBORNE

John Innes Institute, Bayfordbury, Hertford

REPEATED attempts to cross *Solanum demissum* ($2n=6x=72$) with *S. stoloniferum* ($2n=4x=48$) gave one seeded berry containing one seed. This yielded a plant (*M.271*) which had $2n=4x=48$, instead of the expected $2n=5x=60$. The cytological, morphological and biochemical studies of *M.271* reported here provide good evidence that it is a true hybrid and therefore the product of double chromosome reduction.

The plants used in this investigation were as follows: *Parents*. *Solanum demissum* (C.P.C. 2249) (*dms* 2249). This clone, collected by Dr. J. G. Hawkes in 1949 in Hidalgo State, Real del Monte, Mexico, is morphologically typical of the species. It is both male and female fertile, producing 94.6 (± 1.64) per cent stainable pollen of a regular diameter and a mean of 96 seeds per berry on self-pollination. *Solanum stoloniferum* (C.P.C. 2282.2) (*sto* 2282.2). This clone was grown from seed collected by Dr. J. G. Hawkes in 1949 in Puebla State, Mexico. It is a form of the species characterized by dark green leaves, many interjected leaflets, a high leaflet index and blue flowers. It sets abundantly seeded berries by self-pollination.

Hybrid M.271. This one seed obtained in the cross *dms* 2249 (ϕ) \times *sto* 2282.2 (σ) germinated and grew very slowly into a small plant with extremely short internodes and a tufted, almost cushiony habit; it produced only a single flower. By contrast, when grafted on tomato, its

growth was upright and vigorous, it produced long internodes and flowering was profuse and continuous. Comparison of the leaf and flower characters of *M.271* with those of its parents (Table 1) shows that in most ways it resembles the *demissum* parent more closely than it does *sto* 2282.2. A predominance of *demissum* would also be expected in a pentaploid hybrid ($2n=60-3\text{ dms}+2\text{ sto}$ genomes). Morphologically, *M.271* resembles polyploid *S. demissum* ($2n=3x=36$)¹⁻³ and could be taken for one were it not for its chromosome number. An analysis of meiosis gave the results shown in Table 2.

M.271 has no stainable pollen and attempts to back-cross it by both parents as males gave one berry when *sto* 2282.2 was used. This contained two seeds, but neither germinated.

Possible Origins

There is no definite morphological evidence to suggest, let alone prove, that *M.271* is a true hybrid of *S. demissum* \times *S. stoloniferum*. Before giving the biochemical evidence on this point, we may consider three other possible origins, as follows:

(1) *Contamination*. It is possible that *M.271* is a hybrid between *dms* 2249 and a diploid *Solanum*, since three such species, *S. chomatophyllum*, *S. santolallae* and *S. verrucosum*, were growing in the same glasshouse as *S. demissum* and were being used in the same crossing programme. However, all attempts to cross *demissum* with these diploids failed, and, in addition, *M.271* shows no evidence of the characteristic morphology or phenolic pattern (see later) of any of these species. Hybrids between *demissum* and *verrucosum* have been recorded^{4,5}; they differ both morphologically and cytologically from *M.271*.

Table 1. LEAF CHARACTERS OF PARENTS AND HYBRID

	<i>dms</i> 2249	<i>M.271</i>	<i>sto</i> 2282.2
	Mean* (range)	Mean* (range)	Mean* (range)
Pairs of lateral leaflets	2.90 (2-3)	2.00 (0)	3.40 (3-4)
Number of interjected leaflets	2.55 (1-4)	0.90 (0-1)	6.40 (3-10)
Terminal leaflet index (Breadth/Length %)	58 (52-68)	61 (50-72)	66 (60-73)

* Based on ten measurements.

Table 2. MEIOTIC AND FERTILITY DATA

Plant	Meiosis in pollen mother cells							Per cent \pm S.E. stainable pollen
	No. of cells	Mean \pm S.E. per cell					Term coeff.	
		IV	III	II	I	Xta		
<i>sto</i> 2282.2	25	0	0	24.00	0	32.64 \pm 0.51	0.56	60.4 \pm 4.02
<i>M.</i> 271	25	0.08	1.48 \pm 0.25	12.64 \pm 0.36	17.96 \pm 0.40	22.4 \pm 0.73	0.72	0

(2) *Female parthenogenesis*. Polyhaploid plants of *S. demissum* are occasionally produced as a result of female parthenogenesis in selfed progenies of *S. demissum*³ or in progenies obtained from crosses between *demissum* and diploid species^{2,6,7}. All had $2n = 3x = 36$ except for two plants: one which Dodds² found to have $2n = 3x + 3 = 39$ and another which Beamish⁷ found to have $2n = 2x + 2 = 26$.

A tetraploid plant could arise parthenogenetically from a hexaploid only by an extremely abnormal maternal meiosis. Meiosis and embryo-sac development were therefore studied in ovules of *dms* 2249, using sections stained with Heidenhain's haematoxylin. Meiosis was regular and embryo-sac development was of the type normal for *S. demissum*³. Thus the occurrence of a parthenogenetic tetraploid seedling of *demissum* is extremely unlikely.

(3) *Male parthenogenesis*. *M.271* could have conceivably arisen by male parthenogenesis, in which case it would be genetically equivalent to a segregate in a progeny raised by selfing *sto* 2282.2. Such a progeny was grown and all the individuals were found to resemble closely the parent plant; furthermore, all were fertile and set berries by self-pollination. Thus, this parental clone is highly homozygous, and it is therefore inconceivable that a male parthenogenetic seedling should resemble *demissum* rather than its *stoloniferum* parent.

Biochemical Evidence

Except for the anthocyanin pigments of flowers which exhibit dominant-recessive relationships in their inheritance, the genetic control of most chemical constituents is more or less quantitative and hybrids contain most or all of the substances present in the parents⁹. Thus chemical constituents characteristic of presumed parents can give good evidence of the origin of a putative hybrid. On this assumption, the flavonol glycosides of the flowers and the leaf alkaloids of *dms*, *sto* and *M.271* were examined, since these substances were known to show significant variation among the wild tuber-bearing *Solanum* species.

Phenolic patterns in flowers. Ten flavonol glycosides are known to occur (and vary) in potato flowers¹⁰. Their distributions in *M.271*, in its putative parents and in three related diploid species were therefore examined (Table 3). The results eliminate the possibility that *M.271* could have arisen by a chance hybridization between *demissum* and a related diploid species. The following points about the phenolic patterns of the flowers may be noted.

(1) The pattern of *M.271* is identical with that of *demissum*, agreeing with the morphological evidence (see earlier) showing that *demissum* is the predominant parent.

(2) The pattern of *M.271* does not disagree with the idea that *stoloniferum* is the other parent. One constituent of *stoloniferum*, it is true, is not present in the hybrid. This substance, luteolin 7-glucoside, though characteristic of the species, is not always present: it was lacking in four out of 38 clones examined¹⁰. Its absence from *M.271* is therefore not critical.

Table 4. ALKALOIDS IN THE LEAVES

Plant	Alkaloid	<i>R</i> * α -S	<i>R</i> †	Products of acid hydrolysis Aglycone(s)	Sugars
<i>dms</i> 2249	Demissine	0.94	0.29	Demissidine	Xylose, glucose and galactose
<i>sto</i> 2282.2	Solanine	1.0	0.28	Solanidine	Rhamnose, glucose and galactose
	α -chaconine	1.35	0.46		
<i>M.271</i>	Demissine (?)	0.88	0.30	Demissidine + traces of solanidine§	Rhamnose, xylose, glucose and galactose
	New demissidine glycoside α -chaconine (?)	† 1.37	0.48		

* *R** relative to α -solanine: chromatograms run on citrate-buffered Whatman No. 1 paper in butanol-citric acid-water.

† Chromatograms run on silica-gel plates in acetic acid-ethanol (1:3).

‡ Identified as a mixture of two components, since this spot gave a strong Dragendorff reaction for alkaloid but only a weak reaction with Clarke reagent (used for detecting solanidine glycosides in the presence of demissidine glycosides, which do not react).

§ Solanidine was detected, in the presence of demissidine, by the use of Sarett's reagent (compare ref. 13). The crude mixture of alkaloid aglycones failed to respond to the nitroso test, indicating that tomatidine was absent.

(3) The pattern of *M.271* is quite different from those of the three diploid species (Table 2), which makes it very unlikely that any of these species is involved in its parentage. Thus, all three not only contain kaempferol as well as quercetin glycosides but, in addition, the glycosidic patterns (sophoroside, glucoside and (2⁶-glucosylrutinoside)) are quite different from *M.271* or its parents (which have only the 3-rutinoside). Production of (2⁶-glucosylrutinoside) in flowers of *S. stoloniferum* and *S. chacoense* is known¹⁰ to be controlled by a dominant gene *G* (3-rutinoside being the recessive character), and it is unlikely that this glycosidic form would not appear in hybrids involving *chomatophyllum* or *verrucosum*.

Alkaloids of the leaves. Steroidal alkaloids occur, combined with sugars (branched tri- or tetra-saccharides), quite characteristically in the genus *Solanum*, and their distribution has been studied intensively in recent years¹¹. While glycosides of solanidine are widely distributed in the tuberous solanums, those based on demissidine are found only in *S. demissum*. Thus it should be possible to characterize hybrids of *demissum* with other species on the basis of their alkaloid content and this has, in fact been done with *M.271*.

The alkaloids of both parents were examined, with the results shown in Table 4. The clone of *S. demissum* contained the expected demissine¹² and *S. stoloniferum* contained solanine and α -chaconine, the two commonest potato alkaloids. *M.271* contained three glycosides of which two corresponded in *R** value with glycosides from the different parents, that is with demissine and α -chaconine; the third appeared to be a new demissidine glycoside. On acid hydrolysis, these glycosides together yielded demissidine, with traces of solanidine, and four sugars: glucose, galactose, xylose and rhamnose. Thus, *M.271* has the aglycones of both parents and also the constituent sugars of both, since the bound xylose is derived from *S. demissum* and the bound rhamnose can only have come from *S. stoloniferum*.

Since major intraspecific variation in alkaloid content is unknown in the potatoes, this result is effective proof that *M.271* is a true hybrid between *S. demissum* and *S. stoloniferum*.

Origin of *M.271*

The morphology and biochemistry of *M.271* indicate that it is far nearer its female parent, *demissum*, than it is to *stoloniferum*, suggesting that double chromosome reduction occurred in the latter, the male parent.

Meiosis was normal in the sample of pollen mother cells examined from *sto* 2282.2 (Table 1). However, pollen grain measurements from ten different anthers showed a range of size within each anther. Using within-anther variance as a measure of this variation, Bartlett's test showed a highly significant heterogeneity between anthers ($\chi^2_{[9]} 487.4$). Furthermore, the mean variance within anthers of *sto* 2282.2 was above that for other *stoloniferum* clones. Pollen stainability was also extremely variable in *sto* 2282.2, ranging from 12 to 75 per cent per anther. Of a

ample of 1,000 'good' pollen grains 5.6 per cent had diameters equal to or below the modal diameter of pollen grains measured in a diploid species. Since, within species, the size of a pollen grain is often correlated with its chromosome number, it is quite likely that some of the small pollen grains found in *sto* 2282.2 were double-reduced, with 12 chromosomes.

Matsubayashi¹⁴ found that certain clones of *stolonium* produced occasional tripolar spindles at MI of meiosis which resulted in hexads containing six nuclei of almost equal size. Such a mechanism could well be the source of double-reduced pollen grains. Unfortunately, re-investigation of meiosis in *sto* 2282.2 is impossible since the clone was lost through virus infection. There is therefore no information about the cytological mechanism of the presumed double reduction.

Discussion

Double reduction has been invoked on a number of occasions to account for the appearance of unusual hybrids. Thus Steere¹⁵ obtained diploid progeny which resembled both parents, from the cross *Petunia axillaris* $2n=2x=14$ \times *P. hybrida* ($2n=4x=28$). Nishiyama¹⁶ made similar observations on *Avena* hybrids, Karprechenko¹⁷ on *Brassica* \times *Raphanus* crosses and Ewart and Walker¹⁸ on *Poinsettia*. In the cherry, three diploid cultivars are reputed to have arisen from crosses between diploid *Prunus avium* and a tetraploid cultivar, 'May Duke'¹⁹; Darlington²⁰ thought that the chromosome number of the parents disproved the supposed origin of these cultivars but, in retrospect, it now seems that the original interpretation is worth reconsideration.

In none of these examples is there definite proof of double chromosome reduction: for the potato hybrid,

although direct cytological evidence is lacking, the biochemical data appear to be decisive. The fact that Matsubayashi¹⁴ independently obtained a tetraploid plant from the same cross that produced *M.271* suggests that double chromosome reduction may be less uncommon than we think. But it seems unlikely that it is an important general mechanism in Nature for decreasing chromosome numbers.

From a biochemical point of view, *M.271* is particularly interesting since it contains a new hybrid substance, a glycoside of demissidine not present in either parent. The identification of the sugar linkages in this glycoside will clearly be of interest, as it should throw some light on the control of alkaloid glycoside synthesis, about which very little is at present known.

RETICULOCYTE RIBOSOME FRACTION WITH AN EXCEPTIONAL CAPACITY FOR POLYPHENYLALANINE SYNTHESIS

By DR. JOHN O. BISHOP

Institute of Animal Genetics, Edinburgh

RETICULOCYTE ribosomes, isolated from the cell lysate by differential centrifugation, form a heterogeneous population with respect to size¹⁻⁴. The accepted unit is the ribosomal monomer, with a sedimentation coefficient in the region of 80 S (ref. 5). Polyribosomes⁴ (or ergosomes⁶) consist of aggregates of two or more monomers, held together probably by a strand of informational RNA. Two types of ribosomal sub-units are also found, with sedimentation coefficients of about 60 S and 40 S (ref. 3).

It is widely recognized that the monomer is the active unit in protein synthesis. However, the monomers found free in the cell lysate do not synthesize protein²⁻⁴; those ribosomal monomers which make up the polyribosome do so, each monomer synthesizing a single polypeptide chain^{7,8}. In this communication the term 'monosome'⁹ is used to refer to any ribosomal monomer which is not incorporated in a polyribosome. It is convenient to be able to refer in molar terms to the monomers which constitute the polyribosomes, and to the monomers which would be formed by the aggregation of a given quantity of sub-units. The term 'monomer equivalent'⁷ is used to refer to the amount of any given homogeneous or heterogeneous ribosome preparation equal in mass to a ribosomal monomer. The term 'native', used to describe a particular ribosome species, indicates that it was found in the cell lysate. This does not imply that it is present as such within the cell. A 'derived monosome'¹⁰ is one released

from a polyribosome during protein synthesis in the cell-free system. 'Derived sub-units' are sub-units prepared by dissociation of monosomes⁸.

The macromolecular components required for the synthesis of polypeptides under the direction of synthetic polynucleotides are activating and transfer enzymes, transfer RNA, and ribosomes. In the preparations used, the predominant ribosomal species has usually been the monosome. The newly synthesized polypeptide chains are sometimes found associated with artificial polyribosomes which are thought to consist of two or more ribosomal monomers attached to a single polynucleotide molecule¹¹⁻¹⁴. These sediment in a centrifugal field more rapidly than the monosomes¹¹⁻¹⁶. In none of the cases cited has more than a small proportion of the available ribosomal material been seen to become involved in the formation of complexes with polynucleotide. This suggests that only a minor ribosome fraction is capable of reacting with the synthetic polynucleotide.

This conclusion has recently been confirmed by measuring the chain-length of the polyphenylalanine which is synthesized in the reticulocyte cell-free system under the direction of polyuridylic acid (poly U)¹⁷. Total phenylalanine incorporation in this system rarely exceeds 5 μ moles per mg of ribosomes, or, taking the molecular weight of the monomer to be 4×10^6 (ref. 21), 20 phenylalanine residues per monomer equivalent. The average chain-length was found to be of the order of 200 phenylalanine

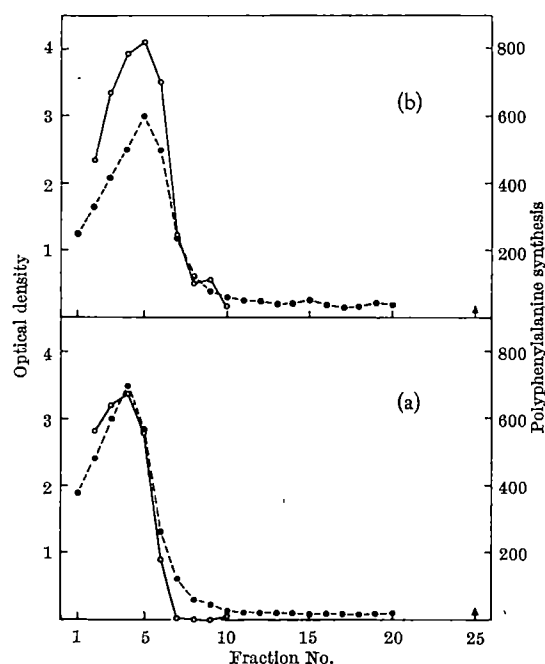

Fig. 1. Polyphenylalanine synthesis by native and derived monosomes following zone sedimentation. (a) Native monosomes. (b) Derived monosomes. The broken lines show optical density at 260 $m\mu$; solid lines show polyphenylalanine synthesis, measured as c.p.m. incorporated per 0.2 ml. under the standard assay conditions described below. The direction of sedimentation is from right to left. The preparation of monosomes is described in the text. One ml. of the monosome fraction, in standard buffer containing 5 per cent sucrose, was layered on a 29 ml., 10–23 per cent sucrose gradient, prepared in standard buffer, and centrifuged for 10 h at 25,000 r.p.m. in the Spinco 'No. 25' rotor at 0° C. Suitable dilutions of fractions 1 to 10 were assayed spectrophotometrically. Fractions 2 to 10 were assayed for polyphenylalanine synthesis in the cell-free system by mixing 0.2 ml. with an equal volume of a solution containing, in μ moles: ATP, 0.25; GTP, 0.08; creatine phosphate, 2.8; $MgCl_2$, 2; *tris*-HCl, pH 7.2, 16; glutathione, 6; 17 L-amino acids, 0.01 each; and uniformly labelled ^{14}C -phenylalanine, specific activity 10 c./mole (approximately 5,000 c.p.m. per μ mole), 0.02, together with 5 μ g creatine kinase, 50 μ g yeast sRNA¹⁵, 25 μ g poly-U and 1.5 mg of an enzyme fraction prepared by precipitating the ribosomal supernatant between 40 and 70 per cent ammonium sulphate saturation¹⁷. The optimum amount of KCl (20 μ moles) was introduced with the gradient fraction. The mixtures were incubated for 40 min at 37° C and chilled. 0.1 ml. of 6 N NaOH was added and after 2 min at 37° C the mixtures were again chilled and 2 ml. of 10 per cent TCA was added. After 30 min at room temperature the precipitates were collected on 2-cm diameter 'Oxoid' membrane filters, washed 8 times with 5 per cent TCA, twice with ethanol/ether (1/1) and once with ether. Radioactivity was measured using a 'Tricarb' liquid scintillation counter, by placing the filter in a 20 ml. vial containing 15 ml. of counting fluid (0.5 per cent w/v PPO, 0.03 per cent w/v dimethyl POPOP in toluene).

residues¹⁷. If one monomer equivalent is involved in the synthesis of each chain, then only 10 per cent of the ribosomal material is active in polyphenylalanine synthesis.

This paper shows that two minor ribosomal species, the native ribosomal sub-units, are very active in polyphenylalanine synthesis. Both types of sub-units are required, together with poly-U. The specific activity of sub-units is 3–4 times greater than that of monosomes. Up to 80 phenylalanine residues are incorporated in the cell-free system per sub-unit pair.

The ribosomes used in these experiments were prepared from rabbit reticulocytes¹⁸. The cells were washed 3 times by centrifugation and lysed by stirring for 2 min at 0° C with 3 volumes of buffer (10 mM *tris*-HCl, pH 8.1 at 0°, 30 mM KCl, 2 mM $MgCl_2$). Lysis was terminated by adding 0.45 times the original cell volume of ice-cold 2 M sucrose. Cell debris was removed by centrifuging for 15 min at 13,000g. Ribosome fraction P1 was the pellet obtained by centrifuging the clarified lysate for 1 h at 30,000 r.p.m. in the Spinco 'No. 30' rotor (78,000g). Measurements made with the analytical ultracentrifuge with Schlieren optics showed P1 to contain polyribosomes and monosomes in the approximate proportion of 2:3, together with a trace (about 5 per cent) of ribosomal sub-units. Fraction P2H was the pellet obtained by centrifuging the lysate for 2 h. The composition of

Table 1 ENDOGENOUS AND POLY-U-STIMULATED PHENYLALANINE INCORPORATION BY RIBOSOME FRACTIONS

Conditions	Fraction P2H	Fraction P2-4
Complete system	0.644	0.219
Plus 40 μ g poly-U	2.895	2.040

One mg of the ribosome fraction was incubated at 37° C for 40 min in total volume of 0.4 ml. containing other reagents in the amounts given in the legend to Fig. 1. The samples were precipitated, collected, washed and counted as described there. Phenylalanine incorporation is presented as n moles of phenylalanine incorporated per mg of ribosomes.

P2H was similar to that of P1, but it contained high proportions of monosomes and sub-units. Fraction P2- was the pellet obtained by centrifuging the 2-h supernatant for 4 h. This fraction consisted largely of monosomes (about 70 per cent) and sub-units (20 per cent), and contained no polyribosomes except for a small proportion of dimers (about 10 per cent). Purified native monosomes were prepared by zone centrifugation: 1 ml. (15–20 mg) of fraction P1 in standard buffer (0.1 M KCl, 1 mM *tris* HCl, pH 8.1 at 0° C, 1.5 mM $MgCl_2$) containing 5 per cent sucrose was layered on a 29-ml., 10–23 per cent sucrose gradient prepared in standard buffer, and centrifuged for 8 h at 25,000 r.p.m. (Spinco 'No. 25' rotor). The bottom 5 ml. of the gradient was diluted with 15 ml. of standard buffer and centrifuged for 3 h at 78,000g to obtain a pellet of purified native monosomes. The pellet from the 8-h gradient contained polyribosomes virtually free of monosomes. These were gently resuspended and 'derived' monosomes were prepared from them by incubation in the complete cell-free system (see legend to Fig. 1). The mixture was diluted with 7 volumes of standard buffer, and a pellet, which contained both derived monosomes and residual polyribosomes, was obtained by centrifuging for 3 h at 78,000g. The derived monosomes were separated from polyribosomes during the subsequent analysis (Fig. 1). 40-S native ribosomal sub-units were purified by centrifuging 1 ml. of fraction P2-4 through a 29-ml. 10–23 per cent sucrose gradient (in standard buffer) for 10 h at 25,000 r.p.m. in the Spinco 'No. 25' rotor. 40-S sub-units were well resolved, but 60-S sub-units appeared

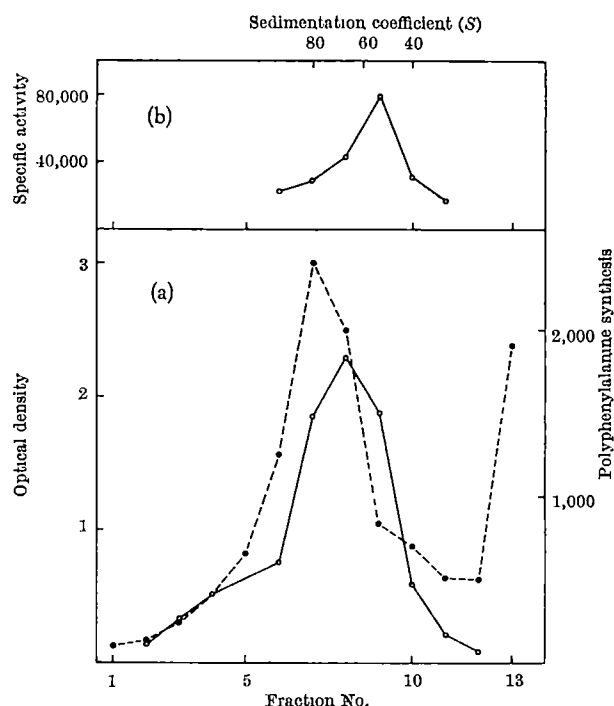

Fig. 2. Polyphenylalanine synthesis by ribosomal fractions following zone sedimentation. (a) Optical density at 260 $m\mu$ (broken line) and polyphenylalanine synthesis (solid line) measured as c.p.m. incorporated under the standard assay conditions described in the legend to Fig. 1. (b) Specific activity, as c.p.m. incorporated per mg of ribosomal material. Direction of sedimentation from right to left. Fraction P2-4 (1 ml.) was applied to a 29-ml sucrose gradient (10–23 per cent) in standard buffer and centrifuged at 25,000 r.p.m. for 5 h. Thirteen 2-ml. fractions were collected and assayed as described in the legend to Fig. 1.

a shoulder on the monosome peak (see Fig. 3). 3 ml. of the 60-S shoulder was applied to a 53-ml. 20-33 per cent sucrose gradient and centrifuged for 10 h at 25,000 r.m. in the Spinco 'No. 25.2' rotor. The 60-S sub-units were resolved from contaminating monosomes and 40-S sub-units as a clear peak near the middle of this gradient (Fig. 4).

Poly-U was synthesized as previously described¹⁷. The preparation used in the experiments had $S_{20,w} = 9.3$, and an average chain-length of about 300 residues, determined by measuring the inorganic phosphate released by bacterial alkaline phosphatase.

The very low polyribosome content of fraction P2-4 is reflected in a low level of endogenous protein synthesis in the cell-free system (Table 1) compared with fraction 2H. In contrast, poly-U-stimulated phenylalanine incorporation was rather higher in fraction P2-4, relative to 2H. Amino-acid incorporation by both fractions, whether endogenous or poly-U-stimulated, was completely dependent on the addition of ATP.

Polyphenylalanine synthesis by native and derived monosomes. Purified native monosomes were centrifuged through a 29-ml. sucrose gradient for 10 h (Fig. 1a). A single peak of optical density was found towards the bottom of the gradient. When the fractions were assayed for their capacity to synthesize polyphenylalanine in a cell-free system with added poly-U the amount of synthesis followed the optical density profile closely. In a parallel experiment derived monosomes were analysed in the same way with similar results (Fig. 1b). However, the specific activity of the derived monosomes was about 10 per cent greater than that of the native monosomes (Fig. 1 and Table 2).

In a previous report¹⁷ it was suggested that polyphenylalanine synthesis by ribosome fractions containing a high proportion of polyribosomes was partly due to monosomes released from polyribosomes during the synthesis of haemoglobin in the cell-free system. Here the activity of derived monosomes is clearly demonstrated. The activity of both types of monosome in this experiment represents

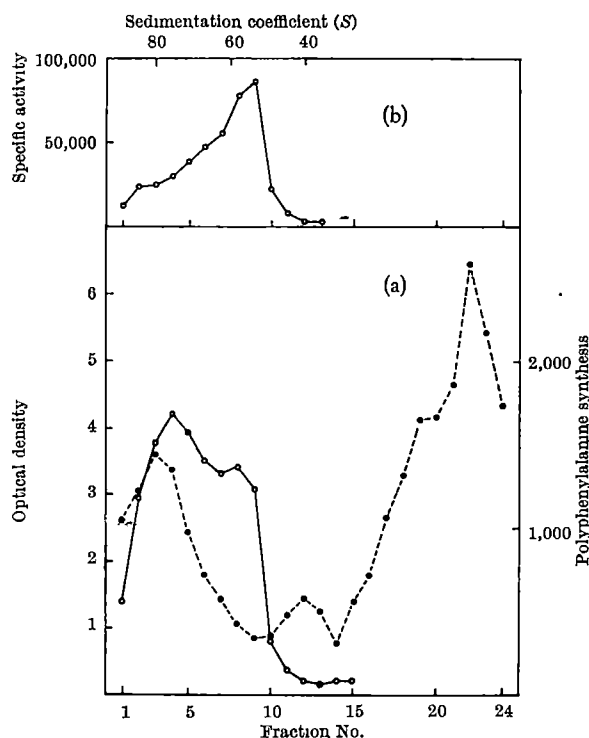

Fig. 3. Polyphenylalanine synthesis by ribosomal fractions following zone sedimentation. (a) Optical density at 260 mμ (broken line) and polyphenylalanine synthesis (solid line). (b) Specific activity. Direction of sedimentation from right to left. Zone centrifugation and assay procedure as for Fig. 2 except that sedimentation was for 10 h and 24 fractions of 1.25 ml. were collected.

Fig. 4. Purification of native 60-S sub-units. Optical density (broken line) and polyphenylalanine synthesis as c.p.m. incorporated per 0.13 ml. in the absence (closed circles) and in the presence (open circles) of 40-S sub-units (5.6 μg). Direction of sedimentation from right to left. The preparation of 60-S sub-units is described in the text. Twenty-eight fractions of about 2 ml. were collected. Assay conditions were as for Fig. 1.

the incorporation of less than 20 phenylalanine residues per monosome. If the average chain-length is about 200 (ref. 17), less than 10 per cent of these monosomes synthesize polyphenylalanine. The lesser activity of the native monosomes most probably indicates that a lower proportion is active; since the derivation of the two types was rather different, it is quite likely that one was more extensively inactivated than the other. However, the alternative interpretation, that the two types of monosome synthesize different lengths of polyphenylalanine, remains as a possibility.

Polyphenylalanine synthesis by native ribosomal sub-units. To determine which components of fraction P2-4 were active in polyphenylalanine synthesis, 1 ml. of the fraction was centrifuged for 5 h through a sucrose density gradient (Fig. 2), bringing the preponderant ribosome species, the monosomes, to the middle of the gradient. Setting the peak optical density at 80 S, the remainder of the gradient was calibrated by the approximation of Martin and Ames²⁰. The 40-S ribosomal units were partially resolved, forming a shoulder at the trailing edge of the monosome peak. Endogenous protein synthesis was measured by incubating aliquots of the gradient fractions with ¹⁴C-phenylalanine in the cell-free system in the absence of poly-U. No significant phenylalanine incorporation was observed. When poly-U was added to the cell-free system extensive phenylalanine incorporation occurred (Fig. 2a). A single peak of activity was found,

The fractions were assayed as described in the legend to Fig. 1. Specific activity is calculated from the optical density and phenylalanine incorporation of the fractions taking the optical density of a 1 mg per ml. solution of ribosomes to be 12 and the molecular weight of the monosome as 4×10^6 (ref. 21).

overlapping the optical density peak, but displaced towards the top of the gradient. The fraction with maximum activity lay between 60 and 70 *S*. A distinct peak of specific activity was also found (Fig. 2b), and the fraction with the highest specific activity lay still nearer to the top of the gradient, between 50 and 60 *S*. In the monosome region (80 *S*) the specific activity was three times lower. The peak fraction, fraction 9, incorporated approximately 60 phenylalanine residues per monomer equivalent (Table 2). Similar profiles, though showing lower levels of incorporation, were obtained when the fractions were incubated with smaller (8 μ g) or greater (80 μ g) amounts of poly-U.

In order to separate the various types of ribosome more completely, a similar sample of fraction P2-4 was centrifuged through the same gradient for 10 h (Fig. 3). Monosomes were found at the bottom of the gradient, clearly separated from the 40-*S* sub-units. The 60-*S* sub-units formed a shoulder on the trailing edge of the monosome peak (fractions 6-8, Fig. 3a). Haemoglobin was partly resolved from heavier contaminating proteins at the upper end of the gradient (fractions 15-24). Aliquots of the gradient fractions were incubated with poly-U and 14 C-phenylalanine in the cell-free system. Two peaks of activity were observed. The first tended to follow the monosome optical density profile, but merged into the second, which was maximum at about 60 *S*. The optical density and incorporation profiles resolved into a single peak of specific activity (Fig. 3b) with its maximum at about 55 *S*. Once again, the specific activity in the monosome region was about three times less than the maximum specific activity (Table 2).

The results show that the ribosomal sub-units are very active in polyphenylalanine synthesis. If both types of sub-unit were required, this would explain the fact that the highest specific activity is found between 40 and 60 *S*, where the two types of sub-unit probably overlap on the gradient. A direct demonstration of the requirement for both sub-units was obtained by mixing fractions from the 10-h gradient. When fractions 7 and 9 were incubated together, polyphenylalanine synthesis was 3.5 times greater than the sum of the two when incubated separately (Table 2). 40-*S* sub-units (fraction 9) showed little activity when incubated alone but the 60-*S* fraction, as isolated from the 10-h gradient, had considerable activity. Since the 60-*S* sub-units were poorly resolved, their activity might be due to contamination either by monosomes or by 40-*S* sub-units. To test this possibility the 60-*S* fraction was applied to a second gradient and centrifuged for a further 10 h. This separated the 60-*S* sub-units from contaminants which appeared as minor peaks on each side of the 60-*S* peak (Fig. 4). At this point the 60-*S* sub-units no longer showed any capacity for polyphenylalanine synthesis when incubated alone, but considerable activity was found when 40-*S* and 60-*S* sub-units were incubated together (Table 2). The profile of polyphenylalanine synthesis in the presence of 40-*S* sub-units followed the optical density profile of the 60-*S* sub-units quite closely (Fig. 4). The greatest specific activity observed in this experiment corresponded to the incorporation of 24 phenylalanine residues per monomer equivalent, which is much lower than the values found in the previous experiments (Table 2). This may be partly because in the assays of the peak tubes the ratio of 40-*S* to 60-*S* sub-units was about 5:1 on a molar basis. In fact, about 60 phenylalanine residues were incorporated per 60-*S* sub-unit present. A second factor may be the inactivation of purified sub-units. Variable inactivation (10-60 per cent) occurred when the sub-unit fractions were held at 0° C for the period of the second gradient run.

These experiments show that native ribosomal sub-units participate with poly-U in the synthesis of polyphenylalanine. Alone, each type of sub-unit appears to be inactive. The obvious inference is that the two types co-operate in the synthesis of each polyphenylalanine

molecule. In these experiments sub-units incorporate up to 80 phenylalanine residues per monomer equivalent. Taking 200 as the chain-length of polyphenylalanine synthesized in the reticulocyte system¹⁷, 40 per cent the sub-units would be participating in polyphenylalanine synthesis, if each chain is synthesized by a single pair of sub-units. If more sub-units were required, the proportion of active sub-units would be higher, and the figure of 80 residues sets at 2.5 the upper limit to the number of pairs which might be involved in the synthesis of a single polyphenylalanine molecule. These arguments are based on the assumption that a given sub-unit can participate in the synthesis of only one polyphenylalanine molecule.

Discussion. The native ribosomal sub-units described here have sedimentation coefficients of about 40 and 60 (ref. 7), as have the derived sub-units prepared by the disaggregation of monosomes⁵. Under conditions which have been reported to effect the reaggregation of derived sub-units⁵, native sub-units are completely stable. Furthermore, native sub-units are isolated from the cell lysate under conditions in which monosomes are stable. These facts suggest that there is an inherent structural difference between native and derived sub-units, although it is clear that before a definitive statement can be made the differently derived sub-units must be compared side by side.

It has not yet been determined whether the native sub-units are in sub-unit form during polyphenylalanine synthesis, or whether they are aggregated together to form monosomes or higher order structures.

The specific incorporation figures for native monosomes and sub-units (Table 2) allow an estimate to be made of the relative contributions these fractions would make to total polyphenylalanine synthesis in cell-free systems. Native sub-units make up about 15 and monosomes about 60 per cent of the total ribosomal material in the clarified lysate (unpublished experiments). In the lysate, about 60 per cent of polyphenylalanine synthesis would be due to both native and derived monosomes, and about 40 per cent to sub-units. The same would be true of purifier systems using ribosome preparations which had been sedimented long enough to precipitate all sub-units, that is for 3-4 h at 78,000*g*. Where shorter sedimentation times are used the proportional contribution of the monosomes will be greater. The same will be true of pre-incubated systems, regardless of the method of preparation, since pre-incubation under conditions favouring protein synthesis leads to the disappearance of sub-units⁷.

E. coli ribosomes have rather different properties than reticulocyte ribosomes, and it is not at all clear what homologies, if any, exist between ribosomes and sub-units from the two organisms. Green and Hall²² isolated sub-units from an *E. coli* lysate which failed to aggregate under conditions which led to the aggregation of derived *E. coli* sub-units. It is possible that these correspond in some way to the native reticulocyte sub-units, but it is not known whether they are active in polyphenylalanine synthesis. Gilbert¹³, and Okamoto and Takanami²³, prepared two types of ribosomal sub-unit from *E. coli* and showed that when incubated together, but not when incubated alone, they would synthesize polyphenylalanine. In each case the sub-units were prepared after the complete dissociation of all monosomes. It is therefore not clear whether the activity observed was due to the derived or the native sub-units.

The question arises of whether native sub-units or monosomes or both are responsible for the initiation of endogenous polypeptide chains, the chains of the globin molecule in the present case. Recent evidence⁷, much of it indirect, indicates that sub-units are required. In certain circumstances a simple one-to-one relationship was demonstrated between the number of sub-unit pairs available and the number of chains initiated. Strong indications were found that monosomes do not initiate endogenous polypeptide chains.

On the other hand, Hardesty *et al.*¹⁰ and Lamfrom andopf²⁴ have suggested that monosomes do initiate globin ins. Under the conditions used by these authors for preparation of monosomes, sub-units would have been aggregated. It is likely, however, that the monosomes are not resolved from the disaggregated sub-units. The monosomes used by Goodman and Rich²⁵ in reaching the conclusion from experiments with an ascites cell stem were more thoroughly purified. However, it is not known whether or not ascites cell native sub-units could be aggregated under the conditions of isolation. The results presented here support the idea that sub-units are active in polypeptide initiation; but at first, they tend to contradict the conclusion that monosomes are inactive. Monosomes are clearly shown to be active in polyphenylalanine synthesis, although less than sub-units. However, it is by no means certain that the properties of poly-U and the endogenous informational RNA are the same. Secondly, in the experiments reported here the ratio of poly-U molecules to ribosomes was of the order of 100:1. In the endogenous situation it is likely to be less than 1:1. The reactivity of the ribosome fractions with poly-U may not be a certain index of their behaviour either within the cell or in the cell-free system without added polynucleotide.

I thank Mrs. Norma Robertson for her assistance, and Dr. B. B. Cohen for his advice. This work was supported by grants from the Medical Research Council.

INTERMEDIATE STATES IN THE PRECIPITATION OF HYDROXYAPATITE

By PROF. E. D. EANES, DR. I. H. GILLESSEN and PROF. A. S. POSNER

Hospital for Special Surgery, Cornell University Medical College, New York

TO distinguish between the physico-chemical and physiological factors underlying the formation of biological hydroxyapatites, investigations have been undertaken in this laboratory on the ageing of aqueous preparation of synthetic calcium phosphates. In these studies, chemical and X-ray diffraction analyses are being employed to elucidate certain aspects of the nucleation and growth dynamics of the emerging solid phase under a wide variety of experimental conditions. The present article describes the precipitation behaviour of these calcium phosphates under conditions of high pH and high initial concentrations of reactants, and gives a description of some of the alterations which occur in the physical and chemical properties of the solid phase while in contact with the preparative solution.

To minimize the formation of more soluble acid phosphates, the following hydroxyapatite preparation, a modification of one proposed by Hayek and Stadlmann¹, was employed: 0.250 molar solutions of $(\text{NH}_4)_2\text{HPO}_4$ were rapidly added while stirring to 0.750 molar solutions of either $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ or $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ to achieve a final phosphate concentration of 0.15 molar in the Ca/PO_4 molar ratio 1.71. All solutions were brought to a pH value of 10.5 with concentrated NH_4OH before mixing. The reactions were carried out at 25° C in closed systems to minimize CO_2 absorption. Constant stirring kept the slurry in intimate contact with the reaction solution for periods up to 2 weeks. Samples of the reaction slurry were withdrawn at fixed intervals after initial mixing for chemical, pH and X-ray diffraction analyses. To avoid changes in the solid during the drying of the slurry, all samples were lyophilized. The samples chosen for chemical studies were washed four times with ammoniated wash water (pH 10.5) before freeze-drying and then analysed for Ca by standard EDTA titration techniques and for PO_4 by the differential spectrophotometric technique of Gee and Deitz². The supernatant and washings were also analysed for Ca and PO_4 .

X-ray diffraction patterns of the samples were recorded on an electronic diffractometer equipped with a scintillation counter and a pulse-height analyser. Nickel-filtered copper $K\alpha$ radiation was employed. The scattering region 24–36°2 θ was principally surveyed; this portion of the diffraction pattern includes the main hydroxyapatite diffraction profile. Because of extensive overlaps, only the 002 peak at 25.8°2 θ was sufficiently resolved for line-breadth measurements. The width at one-half the maximum height of this peak, $\beta_{1/2}$, was measured in degrees 2 θ and corrected for instrumental aberrations according to the method of Warren³. The quantity, $1/\beta_{1/2}$, which is proportional to the mean crystallite size and/or degree of perfection in the direction along the c-axis of the crystals was taken as the measure of the crystallinity index. Since it was observed qualitatively that variations in the degree of resolution of the remainder of the diffraction pattern parallel the changes in the 002 reflexion, this crystallinity index can be taken as representative of the crystal as a whole.

The initial solid phase, which separated immediately on mixing of the reactants, was 'non-crystalline' inasmuch as the diffraction patterns showed no discrete diffraction peaks (see Fig. 1A). The molar Ca/PO_4 ratio of this amorphous phase after washing was well below the 1.71 ratio of the overall reaction system and was found to be dependent on the Ca salt used in the preparation. The molar Ca/PO_4 ratio was remarkably consistent for any given salt; a ratio of 1.52 was found when the nitrate solution was used, a value of 1.46 was observed when the chloride solution was used. At most only 90 per cent of the total Ca available in solution was incorporated into the amorphous phase while the unincorporated Ca either remained in solution or was washed out of the precipitate. No detectable amount of PO_4 was found in either the reaction solution or the wash waters after solid formation.

X-ray diffraction patterns taken on the unwashed, freeze-dried product, as well as patterns taken directly of

the slurry, centrifuged to remove excess water, established that the 'non-crystalline' character of the precipitate persisted in contact with the precipitating solution for several hours before completely transforming into a poorly crystalline hydroxyapatite (Fig. 1B). The observable conversion of the pre-apatitic phase into hydroxyapatite did not occur abruptly, but extended over a period of about 2 h. Measurements made on the 002 diffraction peak of samples collected during this period revealed that even though there was a continuous five-fold increase in relative peak area, indicative of a five-fold increase in converted apatite, the diffraction breadth remained unchanged at $1/\beta_{1/2} = 1.44/^\circ 2\theta$ ($\sigma = \pm 0.04$), a value smaller than normally found in poorly crystallized bone apatite⁴. When the pre-apatitic phase has fully converted, as evidenced by the constancy of the 002 diffraction peak area, a gradual sharpening of the 002 reflexion was observed ($1/\beta_{1/2} = 1.75/^\circ 2\theta$ at 25 h, $1/\beta_{1/2} = 2.39/^\circ 2\theta$ at two weeks).

Increase in the Ca/PO_4 molar ratio of the solid and corresponding decreases in the concentration of solution Ca occurred concomitantly with the crystallographic conversion. By the end of two weeks the Ca/PO_4 molar ratio of the solid had increased to 1.67 ± 0.01 , equalling that for pure hydroxyapatite and the Ca in solution had been considerably reduced from 10 per cent to about 2 per cent of the total Ca available in the solution at the start of the reaction. As before, no phosphate was detected in the reaction solution. An overall Ca/PO_4 molar ratio in slight excess of 1.67 was employed in these experiments to ensure that the final ratio of the solid was independent of the availability of solution Ca. The pH of the reaction solution, on the other hand, dropped from 10.5 to a value of 9.8 immediately on mixing and remained at this value during the entire period of crystallization. The crystal-chemical events described here were greatly accelerated when the reaction was conducted at 30.5°C instead of 25°C .

The ageing of freshly precipitated calcium phosphate as prepared under conditions described in this article can be divided into three stages (Fig. 2). The first stage, which commences immediately on mixing and continues for about 5 h, is characterized by an amorphous-like diffraction pattern which does not undergo any overt changes. Stage two is marked by the progression from a barely discernible apatitic profile superimposed on the amorphous pattern to a fully developed apatite pattern with the complete disappearance of any underlying amorphous features. The third stage covers the period following total conversion of the amorphous phase to a crystalline apatite and is characterized by the constancy of the 002

Fig. 2. The curve connecting the closed circles shows the per cent conversion of non-crystalline to crystalline calcium phosphate (A/A_0) as a function of time. The plot connecting the open circles indicates the drop in solution Ca concentration (mg Ca/ml.) with time.

peak area. This final stage commences about 7 h after the reaction is initiated, and continues indefinitely.

Despite the apparent constancy in the diffraction pattern, the first stage is not chemically static. Slight but significant decreases in solution Ca occur during this period (from 1.20 mg/ml. to 1.02 mg/ml.; Fig. 2). Moreover the demarcation between stages one and two is arbitrarily based on the initial appearance of a discrete apatite diffraction pattern. Since the 002 peak area at the beginning of the second stage is already about 1/5 the value achieved at maximum conversion, it is clear that about 20 per cent of the amorphous material has been converted to the crystalline phase by the time stage two can be detected. Thus, crystallographic as well as chemical changes are taking place in this initial period. Nearly coincident with the emergence of a discernible diffraction profile, however, is a more rapid decrease in solution Ca levels (from 1.02 mg/ml. at the beginning of stage two to 0.42 mg/ml. at the end; Fig. 2). In addition, the 002 diffraction peak, once discernible, proceeds to develop at a rate commensurate with the accelerated rate of fall in solution Ca levels, so that the remaining 80 per cent of pre-apatite converts over a much shorter interval than the initial 20 per cent. One can conclude, then, that while no fundamental distinction may exist between stages one and two, a distinction between rates of conversion can be made with validity, with the crystal phase formation taking place at a much accelerated pace in the second stage than in the first. The constancy of the 002 crystallinity values up to the end of the second stage suggests that the rate of conversion of the amorphous phase in stage two depends on the nucleation of new crystals rather than the growth or perfection of pre-existing crystals.

The most characteristic feature of the third stage is the gradual increase in crystallinity. The improvement in hydroxyapatite crystallinity during this period is typical of the gradual enlargement of mean particle size of many low-solubility precipitates as a result of re-precipitation in solution. This growth of the precipitate, known as Ostwald ripening, is generally attributed to the dissolving of the smaller, more soluble crystals and re-deposition of the dissolved material on the growing faces of the larger, less soluble crystals⁵. No doubt this re-crystallization is in progress from the earliest stages of the conversion, but the time interval in stage two is too short for this gradual increase in crystal dimensions to have a measurable effect on the crystallinity values measured during this period. The gradual decrease in solution Ca from 0.42 to 0.20 mg/ml. during this final stage indicates that a perfection of the crystalline phase parallels the crystal growth.

To describe the initial phase as 'non-crystalline' is to imply only that there has been insufficient development of

Fig. 1. X-ray diffraction patterns of (A) non-crystalline and (B) crystalline (apatitic) calcium phosphates (copper $K\alpha$ radiation).

angular, repetitive, spatial array of ions to define a crystal structure. This does not preclude the possibility of alized order and structure. Indeed, the fact that the lar Ca/PO_4 ratio does not vary under a given set of tial conditions suggests a chemically well-defined local uctural unit.

The formation of 'non-crystalline' calcium phosphate is netic phenomenon. The rapid mixing of the reaction utions creates strong interactions between Ca^{++} and PO_4^{--} ions leading to irregular co-ordination complexes ge enough in size to separate from solution. The bsequent temperature-dependent transformation into atite indicates that this initial phase is isothermally etastable with respect to the more ordered apatite onfiguration. In addition, the sigmoid-shaped relationship the transformation with time strongly suggests that

the conversion mechanism is autocatalytic. It is possible that the interfacial surfaces of the emerging crystalline phase act as sites for heterogeneous nucleation, thereby accelerating the rate of conversion. In this regard, the 'non-crystalline' calcium phosphate remains stable indefinitely if kept dry, pointing out the necessity for water for the process of nucleation to take place in this system.

EFFECTS OF SEEDING ON THE CONDENSATION OF ATMOSPHERIC MOISTURE IN NOZZLES

By DR. E. R. BUCKLE* and DR. A. A. POURING†

Yale University, New Haven, Connecticut

A PRELIMINARY investigation has been made of the effects of inorganic smokes on the condensation of atmospheric moisture in the wind tunnel. The operation of the tunnel, and earlier results obtained with nadulterated air, have been described elsewhere^{1,2}. Theoretical calculations had indicated^{3,4} that chance impurities such as dust particles could not interfere detectably with homogeneous nucleation of the moisture unless present in concentrations of 10^6 particles per c.c. or greater. It was thought desirable to test this experimentally.

In the experiments, smokes of AgCl , AgI , CdI_2 , CuBr , KI , and PbI_2 were generated in the atmospheric inlet of the wind tunnel by evaporation of the compounds on 30-ohm heater coils of nichrome wire. Evaporation rates at various supply voltages were measured by the periodical weighing of test sections of the coils loaded with salt. From 90 to 150 V, the useful range for smoke generation, evaporation was steady and reproducible with a rate of the order of $5 \mu\text{g}/\text{sec}/\text{cm}$ of coil.

Smoke particles were collected for examination by supporting microscope slides and electron microscope grids in the air flow about 10 cm downstream of the smoke generator. The deposit which built up on the support of the pressure probe in the test section was also sampled. Methods of examination included optical and electron microscopy and X-ray diffractometry. Microscopy disclosed a variety of particle sizes. At high heater voltages particles of up to 1μ diam. were present, but at low voltages only sub-micron particles occurred. A useful idea of the relative abundance of small and large particles could be gained with the optical microscope, but the electron microscope was more informative about the structure. In AgI smoke generated at 140 volts there were considerable numbers of 1μ coagula containing up to 20 particles of 0.01μ diam. or less. At 120 V there were fewer large aggregates, sizes below 0.1μ being more frequent. Coagula were rare in smoke produced at 100 V and most of them consisted of only two particles. Nearly all the remaining particles were less than 0.01μ in diam., and even the aggregates were smaller than 0.1μ . It is evident that the total concentration of particles in the smokes increased rapidly as the voltage was lowered because the mass evaporation rate was much the same at

all voltage settings. In cloud chamber experiments it has also been found that AgI aerosols tend to contain coagula when the generating temperature is high⁵.

The course of condensation was followed in two nozzles (Nos. 4 and 6) by measuring the static pressure with an axial probe¹. The air temperature at the inlet was $24^\circ \pm 2^\circ \text{C}$. Mass flow rates of dry air in the nozzles were 972 and 1,110 g per sec respectively. The maximum speed of dry air in the fast nozzle (No. 4) occurred at a Mach number of 1.8. The temperature gradient in this nozzle was approximately 14°C per cm. In the slow nozzle (No. 6) maximum speed was attained at a Mach number of 1.6, the temperature gradient being about 2°C per cm. Other experimental details are given in Table 1.

Typical results are shown in Figs. 1 and 2, where the ratio of the local static pressure, p , to the supply total pressure, p_{01} , is plotted against the position of the probe along the nozzle axis. Positive deviations from the isentropic curves, that is, 'humps', are the result of heat evolved during the condensation of moisture. A level of heat addition exists above which there occurs a normal shock, and this gives rise to a marked peaking in the pressure curves. This critical heat addition depends on the Mach number of the flow in the vicinity of the condensation zone^{1,2}. The positions of shocks in supercritical runs are indicated in the figures.

Seed addition caused the hump to be flattened and displaced downstream. The effect was produced by all compounds and was most drastic in the slow nozzle (curves 644, 645 in Fig. 1 and curves 592, 594 in Fig. 2). In both nozzles the extent of the flattening and displacement decreased as the humidity was lowered. Increase in the voltage of smoke generation also caused a decline in the effect (curves 593, 594 in Fig. 2), presumably through the reduction in the total concentration of seed particles.

Table 1. EXPERIMENTAL DETAILS

Exp.	Nozzle	Relative humidity* (%)	Seed	Heater voltage
601	4	27.0	—	—
602	4	27.0	—	100
644	4	48.0	—	—
645	4	48.0	AgI	100
603	4	74.0	—	—
604	4	74.0	AgI	110

† Present address: Department of Engineering, U.S. Naval Academy, Annapolis, Md., U.S.A.

Conditions for the onset of the seeding effect could not be determined exactly because of the lack of precise control over humidity and smoke concentration. It began at an inlet moisture-level between 27 and 48 per cent relative humidity in nozzle 4 and between 19 and 45 per cent relative humidity in nozzle 6 (Figs. 1 and 2). The exact level was probably highest in the fast nozzle (No. 4). Irregular pressure readings obtained at 34 per cent relative humidity in nozzle 6 (curve 698) were possibly connected with the threshold of the seeding effect, but this needs clarification. From the mass flow rate of air and the evaporation rate of the smoke compound it is calculated that about $10^3/D^3$ smoke particles per c.c. of air were present in the intake, where D is the particle diam. in μ . For the given sizes this means that the seeding effect was observable at concentrations of 10^8 particles per c.c. and above.

The shape of the residual condensation hump in a seeded run, and the location and visual structure (schlieren pattern) of the shock wave (if any) in the hump, were closely similar to those in an un-seeded run at a lower humidity (curves 663, 674 in Fig. 1 and curves 578, 594 in Fig. 2). This leads to the following conclusions. In a seeded run moisture condenses on the smoke particles upstream of the hump, the quantity so condensed depending on the smoke concentration and the flow conditions imposed by the nozzle. The hump is caused by spontaneous condensation, and this process is substantially independent of the preceding heterogeneous process.

It is possible to compare in a rough way the amounts of catalytically and spontaneously condensed moisture by matching humps for seeded and un-seeded runs. Two suitable examples occurred fortuitously in the present

experiments. Curves 663 and 674 (Table 1) show that about one-fifth of the water condensed out on the KI nuclei in nozzle 4 at an inlet humidity of 80.5 per cent relative humidity. The moist air took 120 μ sec to travel down the nozzle from the point at which saturation was reached to the point where the hump began, cooling through 57° C on the way. Curves 578 and 594 show that in nozzle 6 at an initial humidity of 45.5 per cent relative humidity some two-fifths of the moisture condensed out on the AgI. In this case the air cooled through 28° in 400 μ sec while flowing between the saturation point and the hump. Bearing in mind the fall in pressure p/p_0 , decreasing from 0.9 to 0.5 in the first example and from 0.5 to 0.4 in the second, it is seen that termination of the heterogeneous process by the homogeneous occurs sooner the more rapid the expansion.

The fact that the isentropic curve is indistinguishable from the moist air curve in the region where condensation occurs only on the seed shows that this condensation is far more gradual process than the homogeneous one. In the first process, a fixed number only of artificially established nuclei are available, while in the second much larger numbers of natural centres are possible. Apart from the lowering of available moisture the presence of 10^8 seed particles per c.c. has little or no effect on spontaneous condensation, as appears likely from the present results, numbers of self-nuclei exceeding 10^8 per c.c. must build up very rapidly in the beginning of the hump. In fact, since growth of seeded condensate particles is supplanted in this region, multiplication of spontaneous centres rather than their growth is indicated. While nucleation continues in the hump the homogeneous condensate probably consists of particles smaller than the seed (that is, less than 0.01 μ diam.).

The discrepancy between the maxima in curves 663 and 674 suggests that at high-supply humidities the presence of seeded condensate may interfere with homogeneous nucleation. It should be borne in mind, however, that the possibility of disturbance in the flow by the condensation shocks present in these runs throws some doubt on the accuracy of the pressure readings downstream of the shocks. The evaluation of any interference between the condensation processes from pressure data alone would therefore be difficult for super-critical runs.

A reversal of the trend towards sharper humps with higher humidities was observed in un-seeded nozzle expansions of very humid air. This was gas-dynamical in origin², but it is still possible that the inversion shown by curves 664 and 674 was contributed to by differences in AgI and KI as seeding materials. Apart from this, there were no obvious differences in any of the compounds studied.

The high activity of AgI as a catalyst for ice nucleation in water and water vapour has been attributed⁶ to the close matching of the crystal structures. This proposal was recently questioned⁷ on the basis of the limited adsorptive power of AgI for water vapour and the role of surface topography⁸ in heterogeneous ice nucleation. Experiments on the crystallization of ice from water under pressure have since confirmed that for a given substrate material the polymorphic form most closely resembled in structure by the substrate is preferentially nucleated, even when it is metastable⁹.

The chemical influences on the nucleating properties of different compounds are still not clear, and it may be asked whether the results recorded here lead to any new conclusions. The central problem would seem to be whether an ice or a water nucleus first forms on the seed. The X-ray evidence showed that AgI smokes containing large particles were crystalline with the hexagonal structure. Distinction between the hexagonal and cubic forms was obscured for small-particle smokes by the poor resolution of peaks in the diffractometer recordings. Manson¹⁰, whose mean particle size corresponded to the largest single particles in the present smokes (0.1 μ),

Fig. 1. Static pressure ratios for fast nozzle (No. 4) sonic point at 4.5 cm). Curve numbers refer to experiments in Table 1

Fig. 2. Static pressure ratios for slow nozzle (No. 6) sonic point at 8.0 cm). Curve numbers refer to experiments in Table 1

erved that the hexagonal AgI structure gradually loses the cubic as the volatilization temperature is raised. Morphological changes accompanied by an increase in particle size have since been observed in a variety of condensation aerosols on raising the temperature generation^{5,11}. It may be concluded that the hexagonal form of AgI was more abundant in the high-temperature zones. If the nozzle condensate begins as two-dimensional ice nuclei, the greater seeding power of AgI smoke generated at low temperatures would imply that the effect of a decrease in the proportion of hexagonal material is outweighed by the increase in the particle concentration. Alternatively, the topographical requirements for adsorption are likely to be a good deal less stringent generally than those for ice nucleation. The apparent similarity in heterogeneous activity of all the compounds, with the implied unimportance of equilibrium crystal structure, might be more easily explained if, under the conditions of a nozzle expansion, the initial step was the formation of a water layer on the seed.

To recall our main conclusions, it is confirmed that sufficient heterogeneous nuclei are present in normal air to interfere with the homogeneous condensation of water vapour in the wind tunnel. Seeding with foreign particles in concentrations of 10^6 per c.c. or above has a marked effect when the humidity in the intake is raised above

a certain level dependent on the nozzle flow. Under moist climatic conditions, reduction of humidity by seeding makes it possible to study homogeneous condensation in shock-free flow. The experiments provide some idea of the conditions under which spontaneous and catalysed condensation of water vapour occurs competitively. To put this on a quantitative basis to test, among other things, theories of nucleation and growth in aerosols requires further work to establish exact relations between seed concentration, inlet conditions, and flow variables.

METAL CONCENTRATION PROFILES IN OXIDE SCALES ON NICKEL-10.9 PER CENT COBALT ALLOY

By Dr. G. C. WOOD and J. M. FERGUSON

Corrosion Science Division, Department of Chemical Engineering, Faculty of Technology, University of Manchester

FOR many years it has been widely accepted that when nickel is oxidized in oxygen at high temperature a simple, single-phase, single-layer scale of NiO grows on its surface according to a parabolic relationship. The NiO is supposed to be a metal-deficient, *p*-type semiconductor growing by the outward movement of electrons and Ni²⁺ ions to form fresh oxide at the scale/oxygen interface¹. Cobalt behaves similarly above 900° C, but the CoO scale grows much more rapidly², an observation in agreement with measured self-diffusion coefficients of the metal ions in their respective oxides³⁻⁵. Recently, however, the situation has been shown to be more complex because double-layer scales, each consisting of the single oxide, have been found on both metals^{6-13,15}, with the consequence that ideas of oxygen ion or gas movement through parts of the scale have been invoked. The present state of knowledge has recently been reviewed elsewhere¹⁴.

Now, nickel-cobalt alloys, which are homogeneous and single-phase, also produce either single or double layers of a single oxide solid solution (Ni,Co)O when oxidized above 900° C—cobalt being only slightly preferentially oxidized^{14,15}. This almost unique alloy oxidation situation provides an excellent opportunity for following the concentration profiles in alloy and scale directly by electron-probe microanalysis at various stages of growth. The method has problems of its own, but it has some advantages over marker experiments and certain tracer techniques. Such an investigation is reported here because it provides new precise evidence for oxidation of the alloy, with possible interpolation of the results to the case of the pure metals.

Annealed specimens of Ni-10.9 per cent Co, of purity in excess of 99.95 per cent, $2.5 \times 0.6 \times 0.066$ cm, were electropolished at 0.7 amp/cm² (2.5 V) in 60 per cent sulphuric acid (s.g. 1.6) at 30° C for 1 min. After drying, they were immediately oxidized in pure oxygen in a silica-spring thermobalance for 15, 30 min and 1, 2, 3, 6, 10, 24 and 48 h respectively at 1,000° C, followed by cooling over

a 15-min period to minimize scale cracking. Other short-term specimens were simply exposed in flowing oxygen in the hot zone of a furnace for 10 and 15 min respectively without slow cooling. The latter specimens were examined directly in plan in the microanalyser whereas the former were prepared metallographically in cross-section before analysis.

All the specimens gave reasonably reproducible growth kinetics with a close, if not quite exact, agreement with the parabolic relationship (Fig. 1). The growth rate was the same on specimens given a 5-sec etch in 50/50 (v.) glacial acetic acid/nitric acid after electropolishing and was only slightly less on specimens mechanically polished on 600 g silicon carbide paper. The mean parabolic rate constant for the electropolished specimens was 4.9×10^{-10} g²cm⁻⁴sec⁻¹.

Each specimen displayed in section a uniform, single-layer single-phase oxide, generally adherent to the alloy

Fig. 1. Weight gain/time curves for Ni-10.9 per cent Co oxidizing in oxygen at 1,000° C

and with no observable colour change through its depth (Fig. 2). Internal oxide particles were present, but were few in number. The outer surfaces of all specimens examined in plan were blue-grey with characteristic topographical features which will be discussed elsewhere. It is likely that oxide colour in this system is characterized more by grain size than by chemical composition.

Typical microanalyses for the thin scales examined in plan are given in Fig. 3. Since for both films the total wt. per cent metal curves would lie within a few per cent of 78 per cent, the X-ray source was clearly entirely enclosed within the scale over the kilovoltage range used, namely 15–35 kV. As the kilovoltage was reduced, the source became located to a greater extent in the outer region of the scale (the source sizes giving 95 per cent of the radiation were about 0.8, 1.1, 1.5, 1.8 and 2.2 μ at 15, 20, 25, 30 and 35 kV respectively). The results prove that when the surface scale was formed on this alloy it was immediately enriched in cobalt. They also appear to show that this enrichment at the outer surface was greater after 15 min than after 10 min. This could be genuine, but an alternative explanation is that at all

kilovoltages more of the nickel-rich inner region was incorporated in the source for the 10-min specimen because the outer region was quite thin. Plan measurements of this kind permit a more accurate analysis of the outer micron or so of scale than do measurements in section because of their greater resolution.

This general situation is confirmed in Fig. 4, where concentration profiles in cross-section at various stages of oxidation are presented. The profiles are smooth with a pronounced cobalt peak, apparently containing from 16.7 to 22.9 per cent cobalt, near the outer surface. This value is probably rather low, due to relief polishing problems near the outer interface and to the lower resolution of the microanalyser under these conditions

measurements were made at 25 kV). An obvious observation is the similarity in shape of the cobalt and nickel profiles in the films of different thickness, almost as though the cobalt peak were merely growing a longer tail extending to the alloy/oxide interface. Closer scrutiny, however, shows that the outer cobalt-rich peak is in fact growing in thickness and possibly in cobalt content, although the latter effect was small and obscured by the reasons given above. Measurement of the areas under the curves shows that the percentage cobalt in the scales lay between 20.4 and 11.1 per cent, but this varied in a slightly irregular manner with time, probably due to minor measuring errors, and is being studied further. The alloy was depleted in cobalt and enriched in nickel over a small distance.

It is possible to draw several other conclusions from this investigation, some definite but others more tentative and requiring further thought and experiments which are in progress:

(1) The reasonable agreement with a parabolic growth relationship may not be particularly meaningful because of the large compositional variations through the scales. Presumably the cobalt-rich regions offer less resistance to the movement of the diffusing species than the nickel-rich regions because they probably contain a larger percentage of cation vacancies. This is further proof of the need to be careful when carrying out kinetic studies of alloy oxidation. On the other hand, the present situation is really an extreme case of one previously reported for the oxidation of pure cobalt⁵, where it was inferred from marker experiments that the parabolic relationship held even for a non-linear vacancy distribution through CoO. Since the compositions of scale in contact with the alloy and atmosphere respectively did not change much with time in the present case, at least after the first hour and probably from a much earlier stage, it is perhaps reasonable to conclude that the cation vacancy concentration difference across the scale remained constant, which was the only requirement of this type specified in Wagner's original derivation of the parabolic relationship.

(2) As mentioned earlier, at first sight it appears that after the initial cobalt-rich peak was rapidly established, it was pushed further and further from the alloy, fresh oxide being formed near the alloy/oxide interface. This conclusion would support early ideas^{16,17} and more recent revolutionary ones¹⁸ for oxygen ion movement in the scale. However, the gradual growth in thickness and possibly cobalt content of the outer cobalt-rich peak could

only be achieved by the outward diffusion of Co²⁺ ions. There is therefore strong evidence for scale growth by cation movement in the present case, supporting most of the previous evidence with the pure metals. The cobalt peak was constantly reformed, the cobalt and nickel profiles being determined partly by the relative diffusion rates of the cations and partly by thermodynamic factors. It also appears that there was a general outward diffusion of ions and that newly ionized metal did not pass right through the film. Although Co²⁺ ions diffuse about 100 times as fast in CoO as do Ni²⁺ ions in NiO, the closeness of the ionic radii suggests that there should not be any vast difference in their rate in any given composition of (Ni,Co)O. The present direct measurement of concentration profiles in growing scales has certain obvious advantages over marker experiments and tracer techniques, at least in the present system.

(3) Scales on the pure metals almost certainly grow in the same way, by cation movement¹.

(4) Since concentration profiles through single-layer and double-layer scales are very similar¹⁵, this possibly suggests, but does not prove, that they grow by the same mechanism. This would involve cation movement outwards in the inner layer rather than oxygen gas diffusion inwards.

We thank Prof. T. E. Ross for providing facilities and for his advice, Mr. B. W. Lambert for his collaboration with the electron-probe microanalysis and the Science Research Council for the provision of a maintenance grant to one of us (J. M. F.).

STRUCTURE OF THE QUASI-STELLAR RADIO SOURCE 3C 273 B

By M. J. REES and Dr. D. W. SCIAMA

Department of Applied Mathematics and Theoretical Physics, University of Cambridge

IN this article we show that: (1) the radio variations¹ of 3C 273 B are consistent with its red shift being cosmological; (2) the variable component of the optical continuum² of 3C 273 B may be partly due to inverse Compton collisions between relativistic electrons and their own synchrotron radiation. In this case the optical variations would be correlated with the radio variations, though with a phase delay.

The problem involved in (1) is to reconcile (a) the upper limit on the size of the source derived from the period of the variations³; (b) the lower limit on the angular diameter of the source derived from the absence of self-absorption down to some particular frequency^{4,5} (assuming the synchrotron mechanism and that the electrons are radiating incoherently); (c) the distance derived from the red shift of the optical counterpart of the radio source. This problem first arose with the quasi-stellar source CTA 102, which Sholomitsky⁶ reported to vary with a period of about 100 days at 940 Mc/s. In this case the distance

derived from the red shift of 1.037 (ref. 7) is ~1,500 times greater than the upper limit permitted by (a) and (b). We recently proposed⁸ a model of CTA 102 which would resolve this discrepancy, but recognized that it required a rather improbable geometry and so was very implausible. Since then Maltby and Moffet⁹ have reported that CTA 102 did not vary appreciably at 970 Mc/s over a 3-year period ending about 2 years before Sholomitsky's observations began. While it is possible that CTA 102 varies sporadically, the more likely inference is that Sholomitsky's observations are in error.

The same problem arises with the quasi-stellar source 3C 273 B, the flux density of which at 8,000 Mc/s was found by Dent¹ to have increased by about 40 per cent in 3 years. This source shows no self-absorption in its spectrum down to at least 200 Mc/s (ref. 10) (in fact the spectrum is flat down to this frequency). For a magnetic field strength of 10⁻² gauss this implies a lower limit on the angular diameter of 0.03 sec (while the observed¹¹

angular diameter is 0.5 sec). If the period of the radio variations is comparable with that of the optical variations, that is ~ 12 years, the size of the radio source cannot exceed 3 pc and its distance cannot exceed 20 Mpc. On the other hand, the red shift of 0.158 (ref. 12) implies a distance of 470 Mpc.

The discrepancy would be resolved if the varying part of the source had an angular diameter $\sim 10^{-3}$ sec. We therefore propose¹³:

Model I. This model consists of a source of angular diameter 0.5 sec and (roughly constant) flux density ~ 25 flux units down to at least 200 Mc/s, in the centre of which is a varying source of angular diameter 1.3×10^{-3} sec (corresponding to a linear diameter of 3 pc), and at minimum a flux density ~ 2.5 flux units down to the frequency ν_a at which self-absorption sets in. Such self-absorption would not show up in the observed spectrum of this composite source. For a magnetic field H gauss in the central source, $\nu_a \sim 4,000 H^{1/2}$ Mc/s. For simplicity we assume that the central source varies because of an increase in its relativistic electron flux, while its angular diameter and magnetic field are unchanged. If the total flux density of the source is doubled at high frequencies at maximum, the flux from the central source must increase by a factor ~ 10 . Thus the frequency ν_b at which self-absorption sets in at maximum is given by $(\nu_b/\nu_a)^{2.5} \sim 10$, so $\nu_b \sim 10,000 H^{1/2}$ Mc/s.

We can now predict the time variations that would be observed at various frequencies. For simplicity we take the central source to vary sinusoidally at high frequencies. For $\nu > \nu_b$ no self-absorption occurs, so the observed variation would be sinusoidal. In the intermediate range $\nu_b > \nu > \nu_a$ the flux density would at first increase sinusoidally, but when it reaches the level at which it would be self-absorbed at that frequency the increase would be cut off, and the flux density would remain constant until it decreases again in the second half of the cycle. For $\nu < \nu_a$ the variations would be negligible.

A lower limit on H (the value of which has not yet been specified) can be obtained if we require that the energy density of relativistic particles shall not exceed the magnetic energy density. If only ~ 1 per cent of the total energy is in the electrons, we find that the field strength cannot be much less than 1 gauss. If $H = 1$ gauss, ν_a and ν_b have the values $\sim 4,000$ and $\sim 10,000$ Mc/s respectively, and the expected variations at 8,000 Mc/s are large enough to account for the observations. Our estimates for ν_a and ν_b are only rough, but they indicate what might be expected, and the measurement of their values and of the variations at intermediate frequencies would be a useful test of the model and would provide considerable information about the structure of the source.

It is not known how electrons attain relativistic energies in radio sources. The generation process may occur throughout the volume of the source, or the electrons may be ejected from a massive object at its centre. It is easily seen that the electrons must be produced by a mechanism of the former kind if the source in fact resembles Model I. The reason is that the lifetime of an electron which radiates at, say, 10^4 Mc/s in a field of 1 gauss is only $\sim 5 \times 10^6$ sec, which is much less than the time taken to cross the source, even for an electron moving at the speed of light. If such an electron were ejected from the centre it would not reach the edge, unless it were emitting radiation at a frequency at which the source was opaque. Thus for frequencies exceeding ν_a our discussion of the variations will be incorrect. To allow for this we now introduce:

Model II. In this model we assume that the electrons are all generated in a very small region (with diameter < 0.1 pc), which presumably contains a massive object. As in Model I, nearly all the flux at frequencies $< \sim 4,000$ Mc/s is assumed to come from a halo, and we only concern ourselves with an intense spherically symmetric core with radius ~ 1 pc, in which the variable higher frequency

radio flux is supposed to originate. We assume the $H \sim 1$ gauss throughout this region, and that its radiation emission has a flux density $S(\nu)$ which may be variable. For each ν we can determine the minimum radius $R(\nu)$ of a sphere from which $S(\nu)$ could come, if it in fact comes from a region which is opaque at all frequencies up to ν . We find that $R(\nu) \sim 0.3 (S(\nu))^{1/2} (\nu/10^4)^{-1.25}$ parsecs, where S is measured in flux units and ν in Mc/s. This radius can be compared with the distance $r(\nu)$ which an electron radiating at frequencies $\sim \nu$ would travel in its lifetime assuming that it moves with speed $\sim c$. This is $\sim 5 \times 10^{-2} (\nu/10^4)^{-1/2}$ pc. If $R(\nu) > r(\nu)$, electrons moving outward from the centre cannot radiate freely without producing a radiation field the brightness temperature of which a frequency ν is higher than their kinetic temperature. Therefore they will conserve most of their energy until they reach a distance $\sim R(\nu)$ from the centre, where they can radiate freely.

The available data do not enable us to specify the flux density of the core precisely, but it is consistent with the observations to take $S(\nu)$ to be 10–30 flux units in the frequency range from 5,000 up to $\sim 10^5$ Mc/s. $R(\nu)$ is then several times greater than $r(\nu)$ throughout this range, and so we conclude that the radiation at frequency ν comes from the surface of a sphere of radius $R(\nu)$.

If electrons are ejected from the centre at a steady rate, $S(\nu)$ and $R(\nu)$ will adjust themselves to values which depend on the energy spectrum of the input electrons, and the flux of the source will be constant. If, however, the rate of input of electrons alters, $R(\nu)$ (and consequently $S(\nu)$) will change after the lapse of an interval of the order of the time for light signals to travel a distance $R(\nu)$. Thus changes in the behaviour of the massive object will cause changes in the radio flux. The maximum rate of increase of flux will be attained if $R(\nu)$ expands with speed $\sim c$. An increase of $S(8 \times 10^3)$ from 2.5 to 25 flux units, which corresponds to an increase in $R(8 \times 10^3)$ from ~ 0.6 to ~ 1.9 pc, could therefore certainly occur rapidly enough to explain Dent's observations. We can also predict, on the basis of this model, that more rapid variations could occur at higher frequencies. Furthermore, if a sudden change in the rate of injection of particles produces changes in $S(\nu)$ at different frequencies, we would expect to observe the variations at higher frequencies before those at lower (even in the absence of intergalactic dispersion¹⁴).

We have seen that, if the core emits a significant amount of radiation at, say, 10^5 Mc/s, this radiation must come mainly from a sphere which is opaque up to that frequency. The total energy density of all the radio frequency radiation up to 10^5 Mc/s within it will be $\sim 6 \times 10^{-3}$ ergs/c.c. (compared with $\sim 10^{-6}$ ergs/c.c. within Model I), and this very high value suggests that inverse Compton scattering might be important. The Compton lifetime of an electron of energy $\gamma m_e c^2$ in this radiation field is $8 \times 10^9/\gamma$ sec. If $S(10^5) \sim 25$ flux units, $R(10^5) \sim 0.1$ pc and the time which an electron takes to drift out of this sphere is $\sim 2 \times 10^7$ sec if its outward velocity $\sim c/2$. But the electrons radiating at 10^5 Mc/s have $\gamma \sim 300$, and so their Compton lifetime is of the same order. The most energetic photons would result from the scattering of 10^5 Mc/s photons by electrons with $\gamma \sim 300$, and their frequency would be $\sim 10^{10}$ Mc/s, which is in the ultra-violet range. Photons of lower energy (including the whole visible range) would be produced, and the spectrum of the scattered radiation would have a low-energy cut-off at a frequency depending on the smallest value of γ represented in the electron energy spectrum. The energy radiated by this process in the visible range may well be greater than that of the synchrotron radio emission. The exact relative importance of the Compton and synchrotron losses is very sensitive to the high-frequency cut-off in the radio spectrum (which we have taken as 10^5 Mc/s) to the value of H , to the precise position where the electrons are accelerated, and to their mean rate of outward drift. It would there-

re clearly not be worth while to base an exact calculation on this crude model.

The foregoing rough arguments do, however, suggest that at least a part of the visible light emitted by 3C 273 B may have been produced by Compton scattering. Moreover, such a hypothesis would provide a natural explanation for the observed optical fluctuations of the source, since, if electrons are accelerated in the massive object in regular bursts, there will be variations in the intensity of the scattered light. Nearly all the scattering occurs in region of radius ~ 0.1 parsecs (since not only the radiation energy density, but also the particle density, is much higher near the centre). Therefore, fluctuations with time-scales of the order of months, or even less may occur, and these are in fact observed¹⁶. The long period variations³ (~ 12 years) in the optical luminosity may also arise from periodic variations in the rate of injection of electrons, which, as we have already seen, can produce the observed variation at radio frequencies. This model therefore suggests that the radio and the long-period optical variations may be connected.

The increase in the radio flux observed by Dent coincided with a decrease in the optical luminosity, which had the most recent of its 12-yearly maxima in 1962. But according to this model one would expect periodic radio variations to lag (perhaps by several years) behind the variations at the centre which cause them, so this fact also accords with our model, and suggests that the radio variations, when they have been observed for longer, will also turn out to have a period ~ 12 years.

The visible light from 3C 273 B is unpolarized¹⁷, whereas the radio flux (at $\sim 3,000$ Mc/s) is ~ 3 per cent polarized¹⁸. It will not be possible to find out whether the central part of the source is polarized at radio frequencies until the extent to which the degree of polarization changes when the flux varies has been examined. However, even if the radio flux from the core were polarized (implying large-scale uniformity in the direction of H), it would not follow that the scattered visible light must appear polarized, since it is mainly produced in an extremely opaque region, where the radio-frequency radiation will not be polarized even if the field is uniform.

It has been assumed in the foregoing that H does not change significantly when the density of the relativistic particles alters. This will be a good approximation if the magnetic energy is greater than the particle energy (a strength of 1 gauss is sufficient). The field is presumably 'anchored' to the massive object.

It should be emphasized that the Compton losses are significant in this model mainly because of the occurrence of synchrotron self-absorption, which prevents the electrons from radiating away their energy as fast as they otherwise would. Any electrons which are accelerated to high energies ($\gamma > 300$, say), and which therefore emit synchrotron radiation at frequencies which can escape freely from the source, will lose their energy in a time much shorter than the Compton lifetime, so they will contribute to the radiation at high radio frequencies ($> 10^5$ Mc/s), rather than in the far ultra-violet ($> 10^{10}$ Mc/s).

Model III. The first two models have taken no account of the fact that lines are present in the optical spectrum of 3C 273 B. According to Greenstein and Schmidt¹⁹, these lines could be produced by gas of density $\sim 10^7$ particles/c.c., temperature $\sim 2 \times 10^4$ K, and mass $\sim 10^6 M_\odot$. Though this gas need not radiate all the optical continuum, it must be incorporated in a complete model of the source. The model which we shall now describe indicates one way in which this can be done.

If the gas were in the form of a uniform spherical cloud, its diameter would be ~ 0.5 pc, and it would be opaque to light of all frequencies because of scattering by free electrons. It would therefore be difficult to account for the observed fluctuations in optical luminosity with a time-scale of a few months, since if the variable flux were

emitted by a small region within the cloud its variations would be smeared out and would not be observed. This difficulty would be eased if the density within the cloud were non-uniform, or if it had a filamentary structure²⁰, but there would remain the problem of feeding energy into the gas to balance its losses.

In an alternative configuration, suggested by Shklovsky²¹, the gas is distributed in a thin spherical shell. We shall adopt this suggestion, and show that a model can be constructed on the basis of which the radio variations, and both the long and short period optical variations, can be explained.

If the radius of the shell is taken²¹ as $4 \cdot 10^{18}$ cm, and its density as $\sim 10^7$ particles/c.c., its thickness will be $\sim 10^{17}$ cm if its total mass is $\sim 10^6 M_\odot$. The observed broadening of the spectral lines places an upper limit of $\sim 1,500$ km/sec on the velocity of the shell if it is expanding. If there is a mass of $\sim 10^6 M_\odot$ at its centre, a field of ~ 1 gauss would be strong enough to prevent the shell collapsing. Scattering by free electrons would be unimportant at all frequencies. The shell will be transparent to most photons of optical frequency, but will be opaque to radio waves at all frequencies below $\sim 10^5$ Mc/s because of free-free absorption. The observed radio flux must therefore originate outside the shell.

The gas in the shell would produce the observed line emission, and would radiate at a rate $\sim 10^{46}$ ergs/sec, mainly at visible wave-lengths. Its thermal energy content is insufficient to maintain this rate of energy loss for more than a few weeks, and so it must be absorbing energy at an equal rate from the interior. Since the shell absorbs radio waves, intense but unobserved radio radiation may exist in the spherical region within it, and this suggests the possibility that the shell may be absorbing enough energy in the form of radio waves to compensate for its losses in the visible range. This would require the production of $\sim 10^{46}$ ergs/sec at frequencies below $\sim 10^5$ Mc/s, which is ~ 30 times as great as the observed power radiated in this frequency range. However, such a high rate of energy production is not unreasonable since a sphere within which synchrotron self-absorption were taking place at all frequencies up to 10^5 Mc/s would need to have a radius of only ~ 0.8 pc (little more than half the radius of the shell) to emit $\sim 10^{46}$ ergs/sec. Alternatively the required amount could be produced if the whole interior were opaque up to $\sim 7 \times 10^4$ Mc/s. The exact situation within the shell will depend on the energy spectrum of the electrons injected into it, but a sufficiently high rate of energy generation will be achieved if relativistic electrons with $\gamma < 300$ are produced at a rate $\sim 10^{46}$ ergs/sec. We must assume that there is a cut-off in the electron energy spectrum for $\gamma > 300$, since otherwise there would be intense radiation at frequencies above 10^5 Mc/s which would escape through the shell and produce observable radiation with a higher flux-density than is observed.

The observed radiation at frequencies below 10^5 Mc/s (apart from the component which comes from the halo) is, according to this model, emitted outside the shell by electrons which have escaped from the interior. An electron ejected from the massive object at the centre will be absorbing and emitting radiation at the same rate until it approaches the shell. Since the synchrotron lifetime of the electrons (in the absence of self-absorption) is of the order of the time which they take to pass through the shell, most electrons will lose their energy before reaching the exterior. Thus there radiation will not be observed directly, but will simply heat the gas. However, since the power of the observed radio radiation is much less than the power required to heat the gas, the observed radio flux would be produced even if only a few per cent of the electrons succeeded in escaping. Despite the high density of the gas in the shell, an electron passing through it has a 90 per cent chance of reaching the exterior without losing a significant amount of energy in ionization and

collisional losses. If the field ~ 1 gauss extends outside the shell, these electrons will radiate away their energy before they have travelled a further distance ~ 0.1 pc unless self-absorption occurs outside the shell as well. Such self-absorption will occur at sufficiently low frequencies, though the situation is somewhat complicated by the fact that the electrons can radiate energy inwards into the shell.

The production of the visible light is more complicated. Much of it, both in spectral lines and in the continuum, comes from the gas in the shell. However, Compton scattering may also, as in Model II, produce radiation at optical frequencies. The radio radiation energy density in the volume enclosed by the shell is $\sim 2 \times 10^{-3}$ erg/c.c. if synchrotron self-absorption occurs at frequencies up to $\sim 7 \times 10^4$ Mc/s, and the corresponding Compton lifetime of an electron is $2 \times 10^{10}/\gamma$ sec. The highest energy electrons the synchrotron losses of which are balanced by self-absorption have $\gamma \sim 250$, and their Compton lifetimes are of the same order as the time they would take to travel outwards from the centre to the shell. The Compton losses, therefore, are significant, though their exact magnitude is highly sensitive to the precise model adopted. The frequencies of the scattered photons will, as in Model II, be mainly in the visible and near-ultra-violet, and most photons will escape through the shell, though those the frequencies of which correspond to intense spectral lines may be absorbed. Compton scattering of radio frequency radiation outside the shell will be insignificant.

We now consider how the observed variations in flux can occur in this model. We discuss first the long period variations. If there were fluctuations with a time-scale ~ 12 years in the rate of production of relativistic particles at the centre, there would be changes in the radiation density in the sphere enclosed by the shell, and a consequent change in the temperature of the gas. The rate of radiation of visible light by the shell would therefore alter. There would also be changes in the rate at which electrons escape through the shell, and consequently in the observed radio flux. Variations with periods less than, say, 5 years would be partly smeared out and so could not have a large amplitude.

The observed short period fluctuations in the optical luminosity have a time-scale of a few months, and obviously cannot be produced in the shell, which has a radius of ~ 4 light years. In Model II they were attributed to the inverse Compton effect. Since we have shown that light will be produced by Compton scattering in this model, a similar explanation might also be possible here. This would require the scattering to occur in a region smaller than a few light months in radius. However, the scattering will not be concentrated in such a small region as in Model II, where the radiation energy density was high enough for scattering to be significant only within a sphere of radius ~ 0.1 pc. Nevertheless, if all the electrons are ejected from a massive object, their number density will be higher near the centre, and the amount of scattering will be greater there even if the radiation density is no higher. Consequently, the variations in the component of the optical continuum produced by the Compton effect may be sufficiently rapid to account for the observed variations with time-scales of a few months.

We note that whereas the line strengths will alter with the slow period ~ 12 years, it would be inconsistent with this model for them to be involved in the rapid fluctuations in optical luminosity. We understand that attempts are now being made to see whether the lines do in fact vary in intensity. This feature of our model will thus soon be tested.

If we could construct a complete model of this kind, we would be able to calculate the expected phase lag between the variations in luminosity at optical frequencies and the related radio variations. However, we lack sufficient information to enable us to do this. To illustrate the complexity of the problem we enumerate some of the

factors which would determine the magnitude of the lag.

(1) The variations in particle density and radiative energy density propagate outwards with different velocities.

(2) The phase delay of the radio variations will depend on whether self-absorption is taking place outside the shell at the frequency of observation. If it is taking place the observed flux would come from the surface of a sphere with radius greater than 1.5 pc, rather than from just outside the shell, thus increasing the lag of the radio variations. At $8,000$ Mc/s, the frequency of Dent observations, self-absorption would occur if more than ~ 14 flux units of the observed flux density were coming from the compact source (rather than from the halo). Since the observed variations amount to 10 flux units (and this flux cannot come from the halo), it is likely though not certain, that self-absorption is in fact occurring.

(3) The sense in which the emission rate of the gas in the shell varies as the additional radio energy falls on it must be known.

(4) The relative intensity of the light produced by the inverse Compton effect and the light emitted by the shell must be known. These two components will have the same period, but may be out of phase with one another. The times at which maxima in the resultant optical luminosity occur will thus depend on the phase lag between the two components, and on the ratio of the amplitude of their variations.

This discussion shows that existing observations do not suffice to determine a well-defined working model of 3C 273 B. However, we can draw the important conclusion that neither the optical nor the radio variations require the source to be closer to us than the 470 Mpc implied by a cosmological red shift of 0.158 . This conclusion considerably weakens the case for the local model^{3,22} of quasi-stellar radio sources which places them a few megaparsecs away and in which the observed red shift implies a large velocity relative to their surroundings. More detailed observations of optical variations, and of radio variations as a function of frequency, should enable us to decide whether models of the type described here are appropriate for 3C 273 B, and for other quasi-stellar sources as well.

Note added in proof. H. Gent and H. P. Palmer reported at the Dublin meeting of the Royal Astronomical Society (September 7, 1965) that they have succeeded in resolving 3C 273 B at 21 cm with a long base-line interferometer. Their proposed interpretation of their observations is that the source consists of two components separated by ~ 0.4 sec of arc, the angular diameter of each component being less than ~ 0.1 sec. This limit on the angular size of the components is still much greater than the angular diameter of the variable core in our model ($\sim 10^{-3}$ sec), and of the lower limit of 3×10^{-2} sec for the halo.

ASTROPHYSICS

Rotation Period of the Planet Mercury

THE recent radar measurements of Mercury indicate at the period of rotation of the planet is 59 ± 5 days¹. This result is in complete disagreement with the previously noted value of 88 days based on the visual observations of the markings on Mercury²⁻⁶. In this communication we show that the same visual observations can not only be reconciled with the radar-determined rotation period of Mercury but, in addition, can be used to derive an improved value for the period of rotation of the planet, namely, 58.4 ± 0.4 days.

We have examined nearly 50 drawings of Mercury published by Lowell², Antoniadi³, Lyot⁴, Dollfus⁵, and Baum⁶. Of these, six pairs of drawings show near duplication of markings and phase.

	Time-interval <i>T</i> (days)
1) Antoniadi (August 11, 1924) and Antoniadi (June 21, 1927)	1,105
2) Antoniadi (August 23, 1927) and Antoniadi (August 6, 1928)	349
3) Antoniadi (October 4, 1927) and Antoniadi (August 23, 1929)	689
4) Antoniadi (August 6, 1928) and Antoniadi (July 20, 1929)	348
5) Lyot (July 22, 1942) and Dollfus (October 12, 1950)	3,004
6) Baum (March 15, 1952) and Baum (March 1, 1953)	351

Duplication of markings and phase for any single pair of drawings of Mercury does not necessarily indicate that synchronous rotation of the planet is the only possible

solution. A number of other periods of rotation are possible as given by the following equation:

$$P \approx \frac{T}{n + \frac{\theta}{360}}$$

where P is the period of rotation of Mercury in days, T the time-interval between the two observations, n the number of complete rotations of the planet, and θ is the average angular displacement of the earth and Mercury in their orbits, with respect to the stars, in time T . Fig. 1 shows all possible values of P between 50 and 70 days as calculated for each pair of drawings. It is noted that in addition to an 88-day period (not shown in Fig. 1) there are at least three more values of P , namely, 50.1, 58.4 and 70.2 days which will be consistent with all the six pairs of drawings. However, only one of these values is within the allowed limits of radar results (59 ± 5 days). Therefore the rotation period of 58.4 ± 0.4 days is consistent with both the visual and the radar observations of Mercury.

Peale and Gold⁷ have pointed out that because of the large eccentricity of the orbit of Mercury, the tidal torque will be greatest at the perihelion, and the planet will acquire a rotation period lying between 56.6 and 88 days. Our value of 58.4 ± 0.4 days is very close to the lower limit, indicating a significant amplitude dependence of the tidal dissipation on Mercury.

We thank Dr. A. G. W. Cameron for discussions.

Tidal De-spin of Planets and Satellites

RECENTLY, Peale and Gold¹ have shown that the non-synchronous rotation of Mercury is likely to be a consequence of tidal friction. They point out that in an eccentric orbit the spin of an axially symmetric planet will not relax to the orbital mean motion, but instead will approach a final value which is somewhat larger. The final spin rate will be somewhere between the mean orbital angular velocity and the orbital angular velocity at perihelion. The precise value for the final spin is determined by the condition that the net tidal torque on the planet around each orbit be equal to zero. The spin rate at which this condition is satisfied is determined by the frequency and amplitude dependence of the planet's 'Q' ($1/Q$ is the specific dissipation function²). According to Peale and Gold: "The condition discussed here is based on the supposition

Fig. 1. Rotation periods of the planet Mercury, in days, as derived from six pairs of drawings. The single-hatched area shows the limits in the rotation period allowed by the radar observations of Mercury. Visual observations indicate a value of 58.4 ± 0.4 (double-hatched area).

that the solar torque exerted on the tidal bulge exceeds that exerted on any permanent deformation from axial symmetry. In the converse case a period of 88 days for the rotation would indeed result." This last statement, if true, would imply that Mercury's principal moments of inertia, in the plane perpendicular to its spin axis, differ by less than a few parts in 10^7 . This value is very small when compared with the values known for the Moon—another solid, slowly rotating body.

I have re-examined the conditions which determine which of the two final states of rotation tidal friction will bring about. While the conclusions of this investigation cannot be expressed in exact analytical form, good approximations do exist in the limiting case of low orbital eccentricity. These conclusions do not agree with those expressed by Peale and Gold in the statement already quoted here, except for the case of an axially symmetric planet.

As mentioned previously, the vanishing of the net torque on an axially symmetrical planet (the rotation and symmetry axes are assumed to be coincident with the normal to the planet's orbit plane) when averaged over an orbit leads to a final value for the spin, s , which is somewhat larger than the mean motion n . If the figure of the planet has a sufficiently small permanent deformation from axial symmetry, the only new feature which arises is an oscillation of s about its value for the axially symmetric case. Otherwise, if this deformation is large enough, s will eventually begin to oscillate about n and tidal friction will cause the amplitude of this oscillation to decay. Quantitatively, the division between a sufficiently small and a sufficiently large permanent deformation occurs at:

$$\frac{B-A}{C} \approx \frac{2}{3} \left(\frac{s-n}{n} \right)^2 \quad (1)$$

where s is the final value for the spin in the case of axial symmetry. In equation (1), C denotes the moment of inertia about the spin axes while A and B are the smaller and larger of the principal moments about axes perpendicular to the spin axis. For completeness, it should be mentioned that if the initial spin rate of a planet is smaller than its orbital mean motion (this includes retrograde spins) tidal friction may produce synchronous rotation unless the planet's tidal deformation is of the order of its permanent deformation from axial symmetry.

The Moon is unique in the solar system in that its spin has obviously been affected by tidal friction and the value of $(B-A)/C$ for its figure is known. Therefore, for the Moon we may ask the following question: If in its present orbit the Moon were given a much more rapid spin, would tidal friction once again bring the Moon into synchronous rotation? The answer to this question appears to be: No. To arrive at this result we must first calculate $(s-n)/n$ for the Moon. In the special circumstance that Q is independent of both frequency and amplitude, it is easily shown that $\frac{s-n}{n} \approx 9.5e^2$. Taking $\frac{B-A}{C} = 2.05 \times 10^{-4}$ (ref. 3), we find

that the right-hand side of equation (1) is 2.75 times as large as the left-hand side. Thus the Moon would end up spinning with a mean period about 2.86 per cent shorter than its present orbital period and would not return to synchronous rotation. This brings up the question of how the Moon's rotation became synchronous in the first place. To answer this question we would need to know both how the Moon's orbital eccentricity and its principal moments varied in the past. Of course, little can be deduced about the Moon's figure and we shall assume that it has not changed. On the other hand, it is possible to calculate the change in the Moon's orbital eccentricity due to tides. This calculation shows that tides raised by the Moon on the Earth act to increase the eccentricity while tides raised on the Moon tend to decrease it^{4,5}. Without knowledge of the Moon's Q no definite conclusions can be drawn about the sign of de/dt . However, it seems likely that de/dt is positive and e was smaller in the past. This might explain

why the Moon has a synchronous rotation since equation (1) would be satisfied for $e = 0.043$, 22 per cent below present value. Of course, once the Moon attained synchronous rotation this condition would be maintained even though the orbital eccentricity increased. Similar conclusions hold if the Moon's Q is dependent on frequency and amplitude so long as this dependence is not unusually severe.

Equation (1) allows us to derive an upper limit $\frac{B-A}{C}$ for Mercury. The value we obtain (again assuming to be independent of amplitude and frequency) is 0.1 which is undoubtedly much larger than the actual value.

PHYSICS

Laboratory Observations of Plasma Instabilities in a Dipole Magnetic Field

THERE have been a number of laboratory experimental investigations concerning the nature of plasma motion in a dipole magnetic field. Recently results have been reported concerning an investigation of a stable trapped plasma belt in the field of a small, permanent, uniform magnetized sphere¹.

Further investigations using a much larger sphere indicate the existence of plasma instabilities. The experimental arrangement is quite simple. A permanent magnetized sphere, 6 in. in diameter, is placed in a suitable large vacuum chamber and made a negative electrode while the wall of the chamber is made the positive electrode. A d.c. voltage of sufficient magnitude to break down the gas is then applied to the configuration.

When the gas breaks down, a number of plasma configurations occur. The first to be described is that of a stable, visible, plasma belt in the equatorial plane as shown in Fig. 1. As time progresses, an intense arc discharge occurs along a field line as shown in Fig. 2. When the arc occurs the visible belt disappears. The reason that the belt and two arcs appear in the photograph in Fig. 2 is because the picture is a time exposure. After a short time the arc is quenched and the stable belt reappears. The duration of the stable configuration

Fig. 1. Photograph showing stable equatorial plasma belt

increases with decreasing pressure and applied voltage. As the ambient pressure or the applied voltage is increased, both the stable belt and the arcs occur in a continuous manner. Such a condition is shown in Fig. 3.

The points of precipitation of the arcs also vary with applied potential. For large values of applied voltage the points all occur in equatorial regions as shown in Fig. 4.

Buneman² has discussed the various conditions under which instabilities in a streaming plasma can occur. Essentially the theory describes how the directed energy of an electron stream is dissipated in a plasma by collective collisions with ions. The theory treats both random fluctuations and fluctuations caused by the application of a constant field.

Swift³ has applied the theory to a particular model in which the stream is the equatorial ring current and a local electric field transverse to the magnetic field causes a perturbation. The model is applied to geophysical conditions, and the subsequent analysis suggests that, with a large enough ring current, an accelerating potential can be established along a field line provided the conductivity in that direction is not infinite. This potential then serves as an accelerating mechanism for auroral electrons.

Present experimental results indicate that the laboratory model is a particular case of instability arising from the action of a constant transverse electric field. The visible observations in the photographs certainly indicate that a stable configuration first becomes unstable, then returns to its former configuration. Additional evidence

Fig. 2. Photograph showing arc instability. Two appear as a result of 5-sec exposure

Fig. 3. Photograph showing more rapid occurrence of instabilities at higher pressure and voltage. (Darkened area is outline of viewport)

Fig. 4. Photograph showing constriction of precipitation points to low latitudes at high voltage. (Darkened area is outline of viewport)

Fig. 5. Sketch of probe potential versus time. The sharp increase and decrease time-interval is of the order of microseconds. The constant voltage time-interval is approximately 100 msec, while the decrease to initial conditions lasts approximately 50 msec. The wavy portion which indicates the slow rise to instability is of the order of seconds

is also found in the measurement of the temporal dependence of the instability by another method. A Langmuir probe was placed in the stable belt in the equatorial plane. The potential of the probe with respect to the sphere was measured as a function of time. A sketch of a typical oscilloscope trace of the event which is remarkably reproducible in almost all its details is shown in Fig. 5. Starting with the stable configuration, the voltage is seen to increase slowly with time until a critical value is reached. At this potential there is a sharp rise by at least a factor of 5 and a sharp decrease to some value above the stable case. This sharp rise and fall occur in the order of microseconds. There follows a constant voltage regime which lasts for approximately 100 msec during which the arc is sustained. Then the voltage drops to the stable value in approximately 50 msec. The whole process is then repeated. It appears that with proper variation of pressure and voltage the stability conditions can be varied over a wide range.

The present experimental evidence, while incomplete and only moderately quantitative, suggests that much can be learned from further, more extensive, investigations which will include a complete mapping of the temporal and spatial dependence of the instabilities by measurement of electric and magnetic field variations as well as transient current systems. Such investigations are at present in progress.

While the model experiments do not accurately reproduce geophysical conditions it is hoped that a careful experimental study will lead to the formulation of a theory which can then be extended to explain various aspects of auroral phenomena.

Sub-millimetre Wave Spectra of Polar Liquids

IN an earlier communication¹, it was reported that liquid phase absorption of the monohalogenated benzenes at a frequency $\approx 10^{12}$ c/s (1 teracycle) was higher than would be expected from the assumption that a simple Debye process was operative. The measurements supporting this conclusion were made using a CN maser source which gives only the single frequency 29.715 cm^{-1} (337 μ wave-length). We have now supplemented these observations by wide-band spectral investigations using Fourier transform interferometric techniques.

The lower part of Fig. 1 shows results for chlorobenzene in the spectral range 10–400 cm^{-1} . The sharp absorption features at 297 cm^{-1} and 195 cm^{-1} are known molecular vibration bands ν_{24} (B_1) and ν_{30} (B_2), respectively, and are the lowest frequency modes of the molecule². However, the main interest here is the region below 100 cm^{-1} , and in the upper part of Fig. 1 this region is plotted on a logarithmic frequency scale. The microwave observations are those of Poley³ and that of Garg and Smyth⁴, and the interferometric measurements confirm the earlier maser observation. It can be seen that there is a broad but strong feature reaching a maximum at a frequency of 45 cm^{-1} and that the peak is substantially greater than the asymptotic value to be expected at high frequencies from Debye's expression. These observations are believed to be the first reported of a complete band of this type though the high-frequency end of it is to be seen in the observations of Wyss *et al.*⁵. That such bands should exist is not surprising since they may be considered to arise from the

Fig. 1. Far infra-red spectra of liquid chlorobenzene. \square , Microwave observations; \times , teratron observation; ---, interferometer observations; ----, Debye behaviour

Fig. 2. Sub-millimetre absorption of chlorobenzene

'pseudo-lattice' modes of the liquid, and for this there is support from the observations shown in Fig. 2. This shows the absorption spectrum of solid chlorobenzene at a temperature of $\approx 130^\circ$ K with again the liquid spectrum (at room temperature) for comparison. The solid spectrum shows the relatively sharp features characteristic of a lattice spectrum, and it will be seen that these occur in the same frequency region as the diffuse band observed for the liquid. It should also be noted that the absorption in the region below 20 cm^{-1} for the liquid (shown cross-hatched) where Debye processes are dominant is absent in the solid, as is expected since it arises from the overall rotation of dipoles.

The exact nature of the pseudo-lattice in such liquids will be clarified by the results of further work, but the general picture of a polar molecule undergoing resonant oscillations in the force field of its immediate neighbours is acceptable. In such a model, the width of any absorption line would be determined by the lifetime of the pseudo-lattice state or, in other words, the reciprocal of the time over which the surrounding cage does not alter appreciably. This latter is the relaxation time, which is known from viscosity measurements or more directly from the frequency at which the Debye asymptote is nearly achieved. This is about 10 cm^{-1} for chlorobenzene, and it is not hard to believe that the observed band is made up of a number of lines having widths of this order. The well-defined peak of the band is then explained by the reasonable assumption that the orientation of the oscillator in the 'cage' is not random, but has a most probable value which could be similar to that found in the crystal.

METALLURGY

Effect of Temperature on the Discontinuity in the S/N Fatigue Curve of a Stainless Steel

RECENT investigations of the fatigue characteristics of a wide range of alloys have revealed a discontinuity in the S/N fatigue curves at high-stress levels. Finney¹ reports the discontinuities in extruded high-strength aluminium alloys of Australian manufacture to specifications D 683/3 and 2024-T4 involve a shift to shorter fatigue lives at stresses above the discontinuities. These tests were carried out in rotating cantilever machines with notched test pieces ($K_t = 1.5$), and Finney also showed that the size of the discontinuity increases with increasing rate of cyclic loading in tests within the range 100–1,200 c/min. A similar tendency was observed by Williams and Mitchell² in rotating cantilever tests of smooth test pieces prepared in weldable aluminium alloy—'Alean 3032WP'. The discontinuities reported for tests on steels³ show an opposite tendency to increased fatigue lives immediately above the discontinuities, and the trend is similar for both ferritic steel to BS970EN3B and an austenitic stainless steel S130, when smooth test pieces are fatigued in a R.R. Royce fatigue machine.

The strain ageing phenomenon in steels induces special characteristics in their fatigue behaviour, for example, the appearance of a 'knee' in their S/N curves⁴. It has been suggested that the discontinuity is associated with 'cyclic slip' involving a general yielding of the metal due to exhaustion of strain hardening. The plastic deformation involved would induce hysteretic heating in steels and thus cause an increase in both dislocation density and diffusion rates to enhance strain ageing effects. To assess the role of strain ageing during the fatigue cycling of an S130 stainless steel, comparative fatigue tests were undertaken at room temperature and at -80°C . Calculations showed that the diffusion rate would be very slow at -80°C and strain ageing thus suppressed.

The tests were performed in a pull-pull fatigue machine utilizing flat specimens 0.061 in. thick and containing a semi-elliptical hole ($K_t = 2.5$). Figs. 1 and 2 show the results

Fig. 1. Conditions: temperature, $+20^\circ\text{C}$; loading, sinusoidal; frequency, 120 c/s.; stress concentration factor, 2.5

Fig. 2. Conditions: temperature, -80°C ; loading, sinusoidal; frequency, 120 c/s.; stress concentration factor, 2.5

Fig. 3. ($\times c. 666$)

obtained. Testing at -80°C has raised the stress-level of the discontinuity by about 15.9 tons per in.² and the shift of the curve above the discontinuity is to shorter fatigue lives. Metallographic examination of the fatigued stainless steel revealed extensive martensitic transformation at the slip bands (Fig. 3). It appears, therefore, that suppression of the strain ageing phenomenon is associated with a reduced resistance of the stainless steel to fatigue damage at stresses above the discontinuity.

CHEMISTRY

Correlation of the Third Excited State of Polycyclic Aromatic Hydrocarbons with the Ionization Potential

In two earlier communications^{1,2} it has been shown that the means of the first excited singlet state 1L_b and first excited triplet state 3L_a of some polycyclic aromatic hydrocarbons obey the equation:

$$I = 4.39 + 1.15 \frac{^3L_a + ^1L_b}{2} \quad (\text{eV}) \quad (1)$$

where I denotes the ionization potential of the molecule. The designation of the states is due to Platt³.

This equation is similar to the Hückel⁴ equation:

$$I = \alpha + bE$$

where E is the energy of the first state and ' α ' corresponds to the ionization potential of an infinite planar carbon molecule which can be assumed to be graphite, which has an ionization potential of 4.39 eV (ref. 5).

Hückel's theory does not consider electron spin and does not therefore differentiate between states of different spin multiplicity. It does seem that averaging out over the states of different multiplicity brings the experimental data into close agreement with the theoretical predictions.

The third excited states of the polycyclic aromatic hydrocarbons have been examined to see whether they show any correlation. The energies of higher excited triplet states are obtained by the techniques of flash-photolysis^{6,7}. Values of T_3 are listed in Table 1. A plot of I against T_3 is shown in Fig. 1. A very rough correlation only is observed.

The energy of the third excited singlet state can be obtained from absorption spectra. The singlet state corresponding to the T_3 triplet state would appear to be the state designated 1B_b by Platt. This in general corresponds to the level designed β by Clar⁷. In obtaining the values of 1B_b shown in Table 1, the experimental values of Clar have been used throughout. In the case of phenanthrene

and chrysene, theoretical studies by Ham and Rueden⁸ suggest that the levels designated β^1 by Clar correspond to 1B_b and these have been used. The β^1 state has rarely been designated 1B_b for 1,2,5,6-dibenzanthracene it having been found earlier¹ that these were a crossover of the first excited state. In all other cases the state of Clar has been designated 1B_b .

A plot of I against 1B_b is shown in Fig. 1, but no rough correlation can be seen.

Fig. 1 also shows a plot of I against $\frac{^1B_b + T_3}{2}$. A fair good correlation is seen to exist. The equation of the straight line passing through the data is:

$$I = 3.67 + 0.82 \frac{^1B_b + T_3}{2} \quad (\text{eV})$$

using the method of least squares. The sum of the standard deviations is 0.204 where $\frac{^1B_b + T_3}{2}$ is treated as dependent variable.

The best straight line extrapolating to 4.39 is given

$$I = 4.39 + 0.667 \frac{^1B_b + T_3}{2} \quad (\text{eV})$$

The sum of the standard deviations is 0.315.

Hückel's theory predicts a correlation between I_2 , second ionization potential, and the third excited state, not between I and this state. However, the capacitive energy model of Smith⁹, which gives good predictive states that there is a direct linear relationship between I and I_2 which will then explain the correlation shown in equation 2. The capacitive energy model predicts that

$$I \approx I_2 - 4.39 - 3 \times 1.5 \frac{^3L_a + ^1L_b}{2}$$

comparing equation 4 of ref. 9 with equation 1 of this report. This would therefore suggest that equation 3 is more correct one to take, for, as the energy levels go to zero with increasing molecular dimensions, I should go to 4.39, the work function of graphite⁵, the infinite carbon planar molecule. A good test of equations 2 and 3 is the prediction of the third triplet state of benzene. The T_3 state of benzene is 6.94 eV (refs. 7, 8). Equation 2 predicts that T_3 is 6.56 eV whereas equation 3 predicts that T_3 is 7.43 eV. It is hoped to build apparatus¹⁰ which will enable the $T_1 - T_3$ transition of benzene to be measured.

For molecules having ionization potentials in the region of 7–8 eV, which includes nearly all twenty aromatic hydrocarbons listed in ref. 2, either equation can be applied. It is thus possible to predict the T_3 energies of those molecules for which it has not yet been observed. Alternatively, knowing T_3 , the correct assignment of the 1B_b singlet excited state can be made.

In Table 2 are shown the predicted energy-levels of some polycyclic aromatic hydrocarbons assuming 1B_b equal to β and β^1 . In all cases it is more probable that β^1 is 1B_b , but values of β^1 are not available in all cases.

An interesting case is perylene. It has an ionization potential of 7.03 eV (ref. 2) and a T_3 energy of 4.10 eV (ref. 6). Equation 2 predicts a 1B_b energy of 4.09 eV. The spectrum of perylene is greatly different from that of the

er aromatic hydrocarbons⁶. It has a new series of sorption bands denoted α^1 lying between the α - and β -levels. The energy of the α^1 -level is 4.25 eV, which agrees reasonably well with the predicted value of 1B_u . As this level is the third highest energy transition observed in naphthalene, the assignment to 1B_u seems very sensible.

Equations 2 and 3 were computed by Miss E. Watson.

Labelling of Beta-lipoprotein with Tritium

LABELLING of organic compounds and bio-molecules with tritium is of great importance in biochemistry. In general, the method of choice may be radiochemical synthesis¹, the gas exposure labelling of Wiltzsch²⁻⁴, or biochemical synthesis or different types of exchange reactions⁵. However, for the labelling of certain bio-molecules in radiochemically pure form, without any destruction of the natural constitution, only biochemical synthesis could be expected to be successful.

In our laboratory β -lipoprotein was labelled with tritium by a simple exchange reaction in radiochemically pure form, without any change in its natural constitution. The method developed is a modification of that reported by Yavorsky and Gorin⁶, and seems to be widely applicable for the labelling of different types of organic compounds and certain bio-molecules as well.

The tritiating reagent is $\text{CH}_3\text{COOHT.BF}_3 + \text{CH}_3\text{COO}^-$. This complex can easily be prepared by refluxing a small excess of acetic anhydride with tritiated water and saturating the formed trihydride acetic acid with BF_3 gas. The complex was isolated by distillation (b.p. 139°–142° C).

Labelling of β -lipoprotein was effected by simply contacting and shaking it for 24 h with an acetic acid solution of the reagent in heterogeneous phase at room temperature. When the equilibrium was reached, the tritiated complex was decomposed by adding 3–5 ml. of water with subsequent lyophilization. The labile tritium was washed out

Fig. 1. Immunoelectrophoretic pattern of β -lipoprotein of rabbit. B, Above, isolated β -lipoprotein before labelling; below, radio-immunoelectrophoretogram of isolated tritium labelled β -lipoprotein; antisera, the same as A.

with distilled water by repeated lyophilization. The labelled β -lipoprotein was used without any further purification.

Similarly, some other compounds have also been labelled in order to get more detailed information about the scope and mechanism of this labelling method. Results are summarized in Table 1.

Natural β -lipoprotein was isolated by the method of Gofman^{6,7}. The purity of the isolated sample was checked by the immunoelectrophoretic method of Scheidegger⁸ (Fig. 1A). The same control proved (Fig. 1B) that during labelling the β -lipoprotein remained unchanged. The radiochemical purity of the labelled sample was checked by autoradiography using Kodak 'AR-10' stripping film (Fig. 1B, lower picture). The labelled sample could be recovered from aorta homogenate in the same way⁹⁻¹¹ as unlabelled samples after having been administered intravenously into rabbits. The labelled β -lipoprotein has been used for some mechanistic investigation of plaque formation on cholesterol-fed rabbits. More details of this investigation will be published elsewhere¹².

Preliminary experiments made on different types of organic compounds showed that hydrogen atoms bonded to carbon can be replaced with tritium by this reagent (Table 1). The rate of these exchange reactions was found to be markedly dependent on temperature. However, the scope and particularly the mechanism of this exchange reaction require more detailed investigation.

The main advantages of this labelling method are: radiochemically pure labelled compounds can be prepared without any post-labelling purification that may be

required after other labelling methods, for example, after Wiltzsch-labelling⁴. The procedure is rather rapid, requiring no special equipment, and may take place under mild conditions permitting the successful labelling even of sensitive molecules with suitably high specific activity. Activity yield is about of the same order as in the case of Wiltzsch-labelling. Radioactivity was measured by the liquid scintillation technique using a Packard liquid scintillation spectrometer (model 3003).

We thank Dr. S. Virág for the isolation and purity control of the β -lipoprotein sample.

Pure Quadrupole Resonance Frequency Shift and Internal Stress in Gamma-ray Irradiated Sodium Chlorate

THE effects of irradiation and crystalline defect on pure quadrupole resonance (PQR) have been extensively investigated¹. Randall *et al.*² observed an increase of the line width and second moment after X-ray irradiation, and concluded that strain broadening is the predominant mechanism. The changes in the electric field gradient induced by an applied stress were also measured by Collins and Bloembergen³. Colour centres occur in sodium chlorate crystals after γ -ray irradiation. These are probably due to V centres and O_2^- centres^{4,5}. Such impurities are likely to set up stresses and bring about changes in the electric field gradient. For this reason, it would be expected that a shift of the pure quadrupole resonance would occur.

Fig. 1. Temperature dependence of PQR frequency of ^{35}Cl isotope: a, before; b and c, after γ -ray irradiations of 0.9×10^6 and 2.09×10^6 r, respectively

Fig. 2. PQR frequency shift of ^{35}Cl due to γ -ray irradiations

The aim of the work reported here was to measure the shift and to interpret the internal stress. The results of the preliminary measurements are shown in Fig. 1. It was necessary to eliminate the temperature effect. For this reason we made the measurements in a thermostat at about 35°C (ref. 6). In Fig. 1, a is for the non-irradiated sample is for the sample irradiated with γ -rays from reactor TH (Çekmece Nükleer Research Center, Istanbul) with doses of 0.9×10^6 r, and c gives the results after cumulative doses of 2.09×10^6 r. During the measurements the temperature fluctuation was less than 0.01°C . Measurements were made with a conventional Deane-type spectrometer. Frequency was measured with a Hewlett-Packard 524 period counter. For each point on Fig. 1 the mean square root error of frequency was about 30 c/s. In Fig. 2 PQR frequency shift is shown as a function of the irradiation dose. With these results and using theoretical analysis it is possible to interpret the stress produced in sodium chlorate crystals by γ -rays. Since the piezo-electric effect are negligible⁸, and since the changes in the electric field gradient may not explain the line broadening², the main effect should be due to strains. $TE_{33,33}^{E}$ is very much greater than $TE_{33,11}^{E}$. The stress produced by rays of doses 10^6 r in sodium chlorate crystals in the Na-Cl direction is:

$$\sigma_{33} \approx 23 \text{ kg/cm}^2 \text{ Mr.}$$

I thank Dr. S. Akpınar, director of ÇNAEM, and Dr. A. Çilesiz for providing the irradiation facilities.

Acid Phosphatases

WE have been concerned with the isolation of acid phosphatases (orthophosphoric monoester phosphohydrolases, 3.1.3.2.) in quantities sufficient for chemical studies of these enzymes. The sources chosen were: the potato, the human prostate gland and human seminal plasma. We have found that the potato is a poor source and, although the enzyme has been obtained in a form which is homogeneous to starch-gel electrophoresis and to ultracentrifugation, the method is tedious and, because of the very large purification factor involved (about 25,000), leads to a low final yield (about 10 mg from 50 kg of potatoes). The best preparation previously reported was apparently associated with a purification factor of about 1,000 (ref. 1).

Several reports of the complete purification of prostatic acid phosphatase have been made^{2,3}, but, seemingly, the

ounts obtained were too small to allow the usual tests of homogeneity to be applied. It has also been reported that the pure enzyme is unstable² particularly so when in contact with glass surfaces. Recently it has been demonstrated by immunoelectrophoresis⁴ that there are, in fact, two prostatic acid phosphatases. We now report that, by relatively simple and reproducible procedures, two distinct phosphatases can be isolated from a homogenate of prostatic tissue; a typical preparation from thirteen glands giving 25 mg of P_2 and 10 mg of P_1 . Both enzymes are homogeneous in the ultracentrifuge and on starch-gel electrophoresis and are unchanged on further attempts at purification. Both are stable and resist the following procedures: prolonged dialysis, ultra-filtration, gel-filtration, chromatography on cellulose ion-exchange resins, precipitation by salts, filtration through glass wool, prolonged periods (6 months) in solution at 4° interspersed with days at room temperature, low pH (about 2.0) freezing and thawing and contact with certain proteolytic enzymes. Both are unstable above 40° and on precipitation with acetone at 0°.

The assay method used for the enzymes is based on the fact that the ultra-violet absorption spectrum of a monoaryl phosphate differs from that of the parent phenol. For phenyl phosphate (pH 5.0, 0.1 M acetate) the difference in extinction coefficient at 276 mμ is 1,000. Assays are, therefore, conveniently carried out using a solution of phenyl phosphate (5×10^{-3} M) maintained at 35° in a spectrophotometer cell. The specific activity is defined as the rate of change of $O.D._{276}/\text{min}$ produced when 1 μl. of enzyme solution is added to 2 ml. of substrate solution divided by the absorbancy of the enzyme solution at 280 mμ. This assay method is much more convenient and introduces fewer artefacts than aliquot methods based on the formation of molybdenum blue. Greater sensitivity can be achieved by using pyridoxal-5'-phosphate as substrate, but control of pH is then more important since the difference spectrum is very sensitive to pH changes.

Purification starts from an aqueous homogenate of minced tissue. The supernatant is fractionated by addition of ammonium sulphate; the enzymes precipitate between 50 and 75 per cent saturation. The fraction is freed from ammonium sulphate and brought to pH 5.2, 0.02 M acetate buffer. It is then absorbed into a column of DEAE-cellulose which has been equilibrated with the same buffer. After washing with dilute buffer, the column is washed with 0.2 M acetate buffer, pH 5.2. The active fraction is then concentrated by ultrafiltration and passed through 'Sephadex G-100' until its specific activity reaches 0.3. It is then re-chromatographed on DEAE-cellulose under the same conditions as described here except that gradient elution is used. The enzyme emerges as two separate peaks, P_1 coming before P_2 . The specific activities are constant across the peaks and both have the value about 1.2 (this compares with the best value so far obtained with the potato enzyme of 0.4). The enzymes run at slightly different speeds on starch-gel electrophoresis, P_1 running slightly ahead. The Svedberg constants (20°, about 0.5 per cent protein concentration) are 5.23S and 5.36S for P_1 (3 determinations) and P_2 (6 determinations), respectively. Preliminary measurements of the diffusion constants indicate, assuming partial specific volumes of 0.745, molecular weights in the region 120,000–150,000. The rate of passage through 'Sephadex G-100', however, indicates rather lower molecular weights, that is, 110,000–130,000. Amino-acid analyses show some significant differences notably in the relative amounts of valine and alanine. With phenyl phosphate as substrate the two enzymes show similar kinetic behaviour. Both are inhibited by (+) tartrate. An important problem is whether both enzymes occur in each individual gland. In one experiment a single gland was found to contain both enzymes, but it is not yet known whether this is general.

Human seminal plasma might seem, at first sight, to be a convenient source of the prostatic enzymes. Accordingly, a sample of plasma, after dialysis, was chromatographed on DEAE-cellulose as described here. Starch-gel electrophoresis showed that the enzyme obtained, which had a higher specific activity than the prostatic enzymes (about 1.6), was free of contaminating protein. However, activity was found to be split into two bands and, consistently, in the ultracentrifuge the enzyme sample separated into two components, S_1 and S_2 , with Svedberg constant (20°) of 2.65S and 4.43S, respectively. Afterwards a slight change in procedure separated the two enzymes on DEAE-cellulose. These enzymes clearly have much lower molecular weights than the enzymes isolated directly from the prostate and they may not be prostatic in origin. This problem is now being investigated.

The prostatic enzymes and the potato enzyme are inhibited by phosphate ions and by molybdate ions. In all cases the inhibition is kinetically strictly of the 'competitive' type. However, the inhibition by molybdate ions can be reversed by the addition of EDTA, whereas inhibition by phosphate ions is unaffected. The simplest explanation would seem to be that molybdate ions, unlike phosphate ions, combine with the enzyme in a way not directly involving the active site and produce a protein conformation unfavourable for combination with substrates. Consistently, the potato enzyme is considerably activated by EDTA and the effect can be shown not to be due to removal of trace metal inhibitors. These presumed conformational changes should, of course, be detectable by ORD measurements and the appropriate experiments are now in progress.

Structure of Phosphobenzene

WE have already shown that of the polyphosphines of formula $(C_6H_5P)_n$ and melting points (A) 149–150°, (B) 190°, (C) 252–256°, (D) 260–285°, compound A is a five-membered ring compound in the solid state¹.

Compound B, which has been prepared according to the directions given in the literature², crystallizes in at least four different forms; two of these, the monoclinic (from tetrahydrofuran) and rhombohedral (from benzene) modifications, have already been described¹. The other two forms are triclinic and trigonal and have also been obtained by recrystallization from tetrahydrofuran. The triclinic form melted at 185°–189° in an open tube and 193°–198° in an evacuated tube, while the trigonal form melted at 190°–195° in an open tube and 236°–240° in an evacuated tube: all four forms decompose on melting. The only time the trigonal form was obtained the triclinic form was also present. It was not possible to define the conditions which would give any one of the three forms obtainable from tetrahydrofuran. The unit cell and space group data for the trigonal and triclinic forms are: Trigonal: $a =$

13.026, $c = 11.547$ Å, $D_m = 1.265$, $D_c = 1.269$ g/c.c., $Z = 2$, space group $P\bar{3}c1$. Triclinic: $a = 10.551$, $b = 14.717$, $c = 13.000$ Å, $\alpha = 73.7^\circ$, $\beta = 63.2^\circ$, $\gamma = 91.6^\circ$, $D_m = 1.265$, $D_c = 1.266$ g/c.c., $Z = 2$, space group $P1$ or $P\bar{1}$.

We have determined the structure of the trigonal modification by single crystal X-ray diffraction methods. 879 of the 1,397 intensities measured with the aid of a Hilger and Watts linear diffractometer³ were assigned a non-zero value and used in the structure determination. The position of the independent phosphorus atom, obtained from the three-dimensional Patterson function, showed that the six phosphorus atoms in the molecule were arranged in a puckered ring of the chair form. The positions of the light atoms were determined from the $[c]$ -axis projection and a model. The structure was refined by the least squares method with individual anisotropic temperature factors. The final value of R for 879 planes was 0.072. Full details of the structure will be published elsewhere.

The analysis shows that, in the crystalline state, the trigonal form of phosphobenzene *B* is a hexamer, $(C_6H_5P)_6$, and contains a six-membered ring of phosphorus atoms in the chair form with phenyl groups occupying the equatorial positions (see Fig. 1). The molecule has the symmetry $\bar{3}$ (C_{3i}).

Although many attempts were made to prepare suitable single crystals of compound *C*, none was successful. In the only solvent found (diphenyl ether), the suspension had to be heated to refluxing point (258°) to get a clear yellow solution. On cooling only the pentamer, $(C_6H_5P)_5$, could be isolated. This conversion was most probably effected by heat alone, since it is known that, on melting compound *C*, compound *A* is obtained. It has now also been found that compound *A* is converted to *C* by heating in piperidine. Phosphobenzene *C*, m.p. 260° – 265° , has been described as polymeric, but the value of n cannot be very large since an X-ray powder photograph shows it to be highly crystalline. Attempts to index this powder photograph have failed.

It is interesting to note that the related cyclohexyl derivative, $(cyclo-C_6H_{11}P)_n$, is apparently tetrameric as suggested by previous workers^{2,4}. It crystallizes in the space group $P4_3/n$ with $a = 15.33$ and $c = 5.63$ Å. The observed density is 1.161 g/c.c. which, with the cell volume, gives 924.2 for the molecular weight of the cell contents. This implies that there are two molecules of $(cyclo-C_6H_{11}P)_4$ (mol. wt., 456.5) in the unit cell with the molecular symmetry 4 (S_4). The sample used was supplied by Prof. Issleib of Halle.

Fig. 1

Crystals of the sulphur derivative of $(C_6H_5P)_6$, $(C_6H_5P)_6S$ which were obtained from the reaction of phenylphosphine with sulphur (ref. 5) and were identical in every respect with those obtained from *A* and sulphur (ref. 6) (m.p. 148° , mix m.p. 148° , superimposable infra-red spectra), crystallize in the monoclinic system. The space group is either $P2_1$, $P2_1/m$, and a survey of the $h0l$ and $h1l$ intensities suggest that the non-centric $P2_1$ is more probable. The c dimensions are $a = 8.90$, $b = 13.71$, $c = 8.35$ Å, $\beta = 107^\circ$. The observed density is 1.438 g/c.c. which, with the known volume, gives six units (actually 6.005) of (C_6H_5PS) in the unit cell. Since in both possible space groups there may be a minimum of two molecules in the cell, it may be assumed that the molecule is a trimer. Some of the possible structures are:

It is not possible to evaluate a recent paper⁷ describing the synthesis of co-ordination compounds obtained from transition metal carbonyls and what is apparently phosphobenzene *A* until full experimental details are published. Nevertheless the synthesis of $(C_6H_5P)_4Ni(CO)_2$ and $(C_6H_5P)_5Mo(CO)_3$ could be equally well explained by postulating a contraction of $(C_6H_5P)_6$ to give the nickel compound instead of an expansion of $(C_6H_5P)_4$ to give the molybdenum compound. We have made $(C_6H_5P)_6$ in two different ways¹ and have recrystallized it from three different solvents (benzene-alcohol, acetonitrile and tetrahydrofuran) and have always obtained crystals of the pentamer $(C_6H_5P)_5$. Thus it does not appear likely that acetonitrile has any special effect on phosphobenzene as has been suggested by other workers⁷.

BIOPHYSICS

Intercellular Matrix of the Intervertebral Disk in Ageing and in Prolapse

At the present time an increasing amount of attention is being directed to the non-collagenous proteins in connective tissues. Like collagen, these proteins are associated with polysaccharides in the form of mixtures or complexes, though the exact nature of the linkages between the moieties is a controversial subject. These compounds are essential components of the intercellular matrix of intervertebral disks, and a knowledge of them is needed for an understanding of the mechanisms of intervertebral disk prolapse.

Prolapse of intervertebral disk tissue in the lumbar region is a frequent cause of back pain and sciatica. Displacement of tissue follows after the loss of normal mechanical properties. It is known that in connective

es the collagenous fraction of the intercellular matrix associated with tensile strength and the non-fibrillar ion with resilience. The latter fraction requires further investigation.

he term 'herniation of the nucleus pulposus', though occasionally applicable, is an unfortunate misnomer. prolapse is more correct, because the prolapsed tissue consists of varying proportions of nucleus pulposus and annulus fibrosus. Frequently large fragments of cartilage plate are also to be found in sequestered tissue, and misleading to compare the results of analyses on prolapsed tissue with similar investigations on the material removed from the centre of a normal control disk. The significant annular contribution to a disk prolapse is noted in the high collagen content of prolapsed tissue reported by Davidson and Woodhall¹, and Mitchell, Dry and Billewicz².

In a recent investigation on intervertebral disk tissue the main techniques were used, namely X-ray fibre diffraction and electron microscopy³. Subsidiary methods included *in vitro* culture, histology, and biochemical analyses. A wide age range of fresh autopsy specimens (each week of foetal life to 93 years) and tissue removed at the course of 56 lumbar laminectomies for prolapse were examined.

Little direct attention was paid to the polysaccharides because these are poorly crystalline and not suitable for X-ray study by the methods used. However, whenever non-collagenous proteins are discussed the associated polysaccharides are implicated. In human intervertebral disk tissue, at least three non-collagenous proteins have been distinguished from each other by their X-ray fibre diffraction patterns and their appearances in the electron microscope. The differences are slight but quite distinct. In young children the chondrocyte-like cell produces large amounts of a non-collagenous protein. This component has a 'fluffy' appearance when viewed in the electron microscope, indicating that there was a highly swollen gel structure before drying, and the 4.6 Å backbone spacing is a broadened reflexion (Fig. 1). The absence of definite side-chain spacing is notable. By the middle of the second decade the cells produce what has been termed 'mature' β -protein. This is found in quantity in the nucleus pulposus and the transitional zones of the disk, and is present in comparable amounts at all spinal levels; it tends to become more crystalline with advancing age.

After the age of fifty years, and sometimes before, a third non-collagenous protein becomes a major component of disk tissue. In contrast to the proteins mentioned already it gives a better resolved backbone spacing and a well-defined side-chain spacing in the 10 Å region (Fig. 2). When observed in the electron microscope, it was seen to be relatively electron-dense. Since with advancing years this protein becomes a major tissue component, the physical properties of the tissue partly depend on it. Similar fibre diffraction patterns were not obtained in a study of normal articular and nasal septum cartilage, tendon or knee joint menisci³. The central fibro-cartilaginous area of the symphysis pubis from elderly subjects gives a comparable diffraction pattern, and in the electron microscope a similar dense protein has been noted in the media of the aorta. These observations suggest that the presence of this type of protein in certain connective tissues is connected with the demands of physical forces the menisci are non-weight-bearing).

In sequestered disk tissue there is a greater quantity of the mature type of non-collagenous protein as compared with tissue from the interior of the same disk; and in prolapsed disk tissue there is an increase in the non-collagenous protein content as compared with control tissue from the same age range. The tissue gives fibre diffraction patterns in which there is a prominent β -protein backbone spacing but the side-chain spacing is not present, indicating irregularity in the mode of packing of the polypeptide chains (Fig. 3). The chondrocyte-like cells

were observed to be surrounded by large amounts of matrix, apparently of recent origin, suggesting that the increase of β -protein is a change associated with effect rather than cause. Moreover, the overall appearance of the tissue was consistent with a considerable reduction in quantity of the original matrix. The electron-dense protein was infrequently observed in disks where prolapse was present. A number of the specimens were from subjects in the age range where this component begins to be present in appreciable quantities.

Prolapse occurs most frequently in the age range 20-40 years and afterwards becomes decidedly less common⁴. This age distribution alone is sufficient to discount the hypothesis that prolapse is the result of pathologically accelerated ageing of the structure. Such a hypothesis

Figs. 1-3. X-ray fibre diffraction patterns copper $K\alpha$ radiation of wavelength 1.54 Å. Specimen to film distance \approx 3 cm

Fig. 1. X-ray fibre diffraction pattern from the gelatinous nucleus pulposus of a child aged eight years. There is a broadened reflexion in the 4.6 Å region, but no definite side-chain spacing is resolved. The central scatter is from amorphous material. A weak reflexion at 2.86 Å is present from collagen

Fig. 2. X-ray fibre diffraction patterns from nuclear material of a subject aged 87 years. A well-defined β -protein diffraction pattern is present with clear resolution of the side-chain spacing. There is no evidence of orientation

Fig. 3. Comparison X-ray fibre diffraction patterns of prolapsed lumbar disk tissue (left) and nucleus pulposus from an elderly subject (right). The difference in the sharpness of the backbone spacings is evident. The non-collagenous protein in the prolapsed tissue has not given a side-chain spacing. (The region outside the collagen side-chain spacing is 'clean')

was tentatively supported by Blakely *et al.*⁵, who also observed an increase in the β -protein content of prolapsed disk tissue, although they assumed that this was due to the same protein as is prominent in the disks of elderly subjects. Lyons *et al.*⁶ reported the results of biochemical investigations during which they isolated an 'insoluble complex' from the disks of subjects over the age of 60 years taken as normal controls, and a 'similar type of complex' from eight 'herniated' specimens. Both complexes contained chondroitin sulphate *B*. These authors also supported the theory of pathologically accelerated ageing. The hexosamine/nitrogen ratios they reported for the insoluble complexes showed wide variations which could well be indicative either of a mixture or inconstant composition.

The changes in the intercellular matrix are, in the main, a reflexion of cell activity. In prolapse the polysaccharide content is reduced^{1,2} and the non-collagenous protein content increased, an alteration in the quality as well as the quantity of the matrix. This indicates disordered cell function, which may well stem from a disturbed nutritional state similar to that which has been proposed as a cause of osteoarthritis. No differences have been detected between the tissue from patients with or without a history of a significant spinal injury. In ageing there is also a change in the type of matrix, with the emergence of the dense β -protein as a major matrix component. Once this is present in appreciable quantities it seems reasonable to suggest that it affords a measure of protection against prolapse.

BIOCHEMISTRY

Enzymatic Synthesis of the Skin-lightening Agent, Melatonin, in Amphibians

MELATONIN (*N*-acetyl-5-methoxytryptamine) has been shown to be the most effective skin-lightening agent in amphibians^{1,2}. This compound produces changes in pigmentation by causing the aggregation of melanin granules within the amphibian melanocyte. Although melatonin has been found to occur in mammals, no evidence for its formation has been obtained in amphibians where it exerts its most potent effects. High concentrations of radioactivity have been observed in the pineal area of the amphibian *Xenopus laevis* after the administration of the melatonin precursors ¹⁴C-5-hydroxytryptamine and ¹⁴C-methylmethionine³.

The formation of melatonin is catalysed by an enzyme, hydroxyindole-*O*-methyl transferase, which requires *N*-acetylserotonin as the substrate and *S*-adenosylmethionine as the methyl donor⁴. So far, this enzyme has been found only in the pineal gland of mammals⁵ and birds⁶. In mammals melatonin has been shown to inhibit the oestrous phase of the rat oestrous cycle and to produce decreases in ovary weight⁷. This communication describes the presence of hydroxyindole-*O*-methyl transferase in two amphibian species, *Xenopus laevis* larvae and adult frogs (*Rana pipiens*).

Table 1

Species	Hydroxyindole- <i>O</i> -methyl transferase activities
<i>Xenopus laevis</i> larvae	1.3
<i>Rana pipiens</i> adults:	
Brain	11.6
Pineal area	36.6
Optic tectum	34.5
Hypothalamus	36.0

Results expressed as μ moles/¹⁴C-melatonin formed per g tissue per hour when incubated with *N*-acetylserotonin and ¹⁴C-methyl-*S*-adenosylmethionine.

Xenopus larvae, stages 48–50 (ref. 8), were homogenized in 0.5 ml. ice-cold water using an all-glass homogenizer. A 0.2-ml. aliquot was taken to measure the hydroxyindole-*O*-methyl transferase activity⁹. A control incubation was run concurrently without the addition of substrate correct for a small amount of endogenous material present in the *Xenopus* larvae which forms a methylated metabolite on incubation of *Xenopus* larvae with *N*-acetylserotonin and ¹⁴C-methyl-*S*-adenosylmethionine, a radioactive product was formed which was extractable into chloroform. This material had the same *R_F* value on three thin-layer chromatographic systems as authentic melatonin. The amount of melatonin formed enzymatically (Table 1) was more than enough to cause blanching in the *Xenopus*².

Hydroxyindole-*O*-methyl transferase was also examined in the adult frog brain using the procedure already described. Considerable enzyme activity was found in the frog brain (Table 1). Since the brain would also include the pineal, hydroxyindole-*O*-methyl transferase was measured in several brain areas. All areas examined contained enzyme activity. The melatonin-forming enzyme was found to be absent in the adult frog skin, liver, intestine and heart. These results demonstrate that the enzyme that forms the amphibian skin-lightening agent, melatonin, is present in the brain and pineal area of the frog, while it is present only in the pineal gland of other mammalian and bird species so far reported. Further discoveries and more detailed analyses of hydroxyindole-*O*-methyl transferase activities in pineals, brain regions and eyes in various vertebrate species will be published elsewhere.

Agar-gel Electrophoresis of Soluble Lens Proteins in Galactose-fed Rats

A NUMBER of reports have recently been published dealing with the electrophoretic properties of water-soluble lens proteins of albino rats and the presence of a 'fast' anodic fraction in electrophoretic patterns of lens proteins from galactose- and lactose-fed rats^{1,2}. It is well established that dense cataractous opacities develop in rat lenses within two to three weeks of galactose feeding³. Electrophoretic analysis of such lens extracts shows that the fraction with the highest anodic mobility is con-

erably increased when compared to normal rat lens⁴. There is, furthermore, an overall decrease in fractions migrating toward the cathode.

Occasionally, however, a rat will not develop a severe opacity of the lens despite prolonged feeding with large amounts of galactose. In some instances the typical cataractous opacity is present in one eye only, while the other lens remains clear.

In an attempt to correlate the appearance of the 'fast' anodic fraction with the stage of cataract development, the following experiments were carried out. From a colony of approximately 100 male Wistar rats, which had been placed on a 40 per cent galactose diet, the following two animals were chosen at random from their respective groups: one rat from the group with mature bilateral cataract after 21 days of galactose feeding, and one rat from the group that had developed only a unilateral cataract. The rat from this second group had been on the lactose diet for 14 days during which time a nuclear opacity developed in one lens while the fellow eye remained clear. One rat of the same strain and comparable age, which had been fed normal laboratory rat chow, was selected as control animal.

After killing the rats under light ether anaesthesia, the lenses were immediately extracted from the eyes under a dissecting microscope and washed free of vitreous humour in iced physiological saline. Along with the dissection a schematic drawing was made of each lens to indicate the degree of cataract development. The lenses were then homogenized individually in 50 μ l. iced saline in a small porcelain weighing-pan, using a glass rod as pestle. The homogenate was transferred quantitatively into a micro-haematocrit capillary tube, using an additional 50 μ l. of saline to rinse the spoon. The haematocrit tube was then sealed and centrifuged in a micro-haematocrit centrifuge for 4 min at 4° C. Following centrifugation, the supernatant was used for electrophoresis.

Agar-gel electrophoresis was carried out following Grabar's method⁵, in a medium of 2 per cent agar in 0.025 M barbital buffer, pH 8.9, and 4 m.amp per cm for 5 min at room temperature. Immediately upon completion of electrophoresis, the agar slides were transferred into a staining bath of 0.05 M thiazine red in 5 per cent acetic acid. After staining for 1 h, excess dye was removed by washing in 5 per cent acetic acid with the final rinse containing 2 per cent glycerol in 5 per cent acetic acid.

Fig. 1 shows the results of the electrophoresis. The two patterns represent lens protein extracts from the normal control rat, right and left lens being indicated at the cathodic side of the slide by R and L, respectively. The drawings next to the electrophoretic patterns indicate the appearance of the lenses under the microscope. As expected, the normal lenses were absolutely clear.

The next two patterns are those obtained from the lens extracts of the rat with mature bilateral cataract. These patterns correspond exactly to those which we obtained repeatedly when using pooled lens extracts from galactose-ataractous rats. The drawings show the presence of a dense opacity in the centre of the lens with small vacuoles in the periphery. Electrophoresis revealed a decrease in the cathodic fractions as well as a considerable increase in the fraction nearest the anode.

The third set of patterns stems from the lens extracts of the rat which had developed unilateral cataract after 14 days on galactose. The dense opacity in the left eye is smaller than that of the other rat due to the shorter feeding time. However, though the left lens still contains a normal amount of the cathodic fractions, the change in anodic fractions is already present. The right lens of this animal was perfectly clear except for a few isolated vacuoles along the periphery. The electrophoretic pattern of this lens is normal in appearance.

A sample of normal rat serum was electrophoresed along with the lens extracts to provide a reference marker. The serum protein pattern, indicated by the letter S, appears

Fig. 1. Agar-gel electrophoresis of individual rat lens proteins. Right and left lens of the same animal are indicated by R and L, respectively. Drawings next to lens protein patterns at cathodic side show stage of cataract development as appearing under dissecting microscope at time of lens extraction. Anode at right. From top to bottom: (a) Normal rat; (b) rat with mature cataract after 21 days on galactose; (c) rat with unilateral cataract (left lens) after 14 days on galactose; (d) normal rat serum.

at the bottom of Fig. 1, the albumin showing at the right-hand side.

Throughout our experiments, 38 out of 635 galactose-fed male Wistar rats, or roughly 6 per cent, did not develop bilateral cataract, even when feeding with galactose was continued for 4 weeks. The development of dense nuclear opacities in those rats was inhibited either in both eyes or in one eye only. There was, furthermore, no consistency as to which eye was affected when unilateral cataract was present. When the extracted clear lenses were examined under the dissecting microscope, the apparently unaffected lens showed the formation of vacuoles similar to those presented in Fig. 1.

In this work, the development of a unilateral cataract made it possible to use the clear fellow lens as a control, thus eliminating differences between animals. It raises the question whether a protective mechanism could be involved, lessening the effect of galactose on the metabolism of the rat lens. Why this should occur in one lens and not in the other is even more puzzling.

This work was supported by research grant NB-03443 from the National Institute of Neurological Diseases and Blindness, National Institutes of Health, U.S. Public Health Service.

Freeing of Amino-acids from Proteins

The large amount of free amino-acid which surrounds haemoglobin freshly released from red blood cells cannot be dialysed away from the protein even after vigorous washing (48 h, running water). The amino-acids still released after such washing may come from (a) metabolism of bacterial contaminants, (b) cellular enzymes,

Table 1

Time from completion of autoclaving (min)		Amino-acid released into dialysate from:		Time from completion of autoclaving (h)		Amino-acid released into dialysate from:	
		Bag A	Bag B			Bag C	Bag D

13.5 h overnight		9	42*				

Amino-acids expressed as μg of nitrogen in 100 ml. of dialysate.

* These dialysed against normal saline.

(c) amino-acids secondarily bonded to the protein, and (d) the cleavage of peptide bonds. It is impossible to rule out (a) and (b) in the case of haemoglobin.

Commercial casein, however, makes solutions with water which will withstand autoclaving (15 lb. per sq. in. for 30 min) without coming out of solution. A solution of casein subjected to this treatment does not have a large pool of amino-acids around it, but it does progressively release amino-acids on dialysis. (20 g of soluble casein (B.D.H.) were slowly added to 400 ml. of water at 30° C. 25 ml. of this solution contained 150 mg of nitrogen and was put into 'Visking' tubing double knotted at each end. These bags were immersed in water and autoclaved. They were dialysed against 100 ml. of liquid. Each dialysate was evaporated to dryness (1 g sodium chloride was added to the aqueous dialysates first, in order to standardize extraction). After extraction into acetone-hydrochloric acid mixture, which was removed at 120° C, the amino-acids were estimated by the method of Moore and Stein¹.) The autoclaving must exclude those having been produced by causes (a) or (b)².

The amount of amino-acid produced is always small, but it increases significantly if the dialysis is against normal saline instead of water. This is shown in Table 1, as is also the continual production of free amino-acids. The quantity released is in some way related to the concentration of amino-acid in the surrounding solution since the amount freed after 15 h dialysis against 100 ml. of unchanged water is no greater than the sum of the amounts given off during four successive half-hour dialyses.

The freeing of more amino-acids by salt was first noticed with solutions of haemoglobin. While in the present report on casein the cause (c) cannot be excluded, the evidence is in favour of the rupture of primary bonds.

Red Pigment in Leaf Galls of *Salix fragilis* L.

THE galls of *Salix fragilis* L. leaves are produced by *Pontania proxima* Lep. and contain a red pigment which is not present in mature leaves or leaves freed from galls, but has been found in young leaves¹. Pigment production has been stimulated in young willow leaves by slight mechanical injury, but the injured leaves generally died². Pontanin was isolated as orange-yellow needles from the galls of *S. fragilis* dried at 100° C and on hydrolysis gave 1 mol. of purpurogallin and 2 mol. of glucose, the probable formula being $\text{C}_{23}\text{H}_{28}\text{O}_{15}$ (ref. 3). Related glycosides of purpurogallin were isolated from other dried galls³, but it was uncertain whether these compounds were natural products or artefacts, and from unpublished

work⁴ it was evident that fresh galls from one of the species lacked purpurogallin glycosides. Hence the present work was done with a fresh approach to clarify the identity of the pigment as part of a larger investigation.

The pigment was extracted from the fresh galls of *fragilis* leaves by maceration with methanol containing 1 per cent hydrochloric acid, the extract concentrated a few ml. under reduced pressure, and purified by the method of Harborne⁵ on washed sheets of Whatman N 3MM paper by band chromatography, using *n*-butanol-2 N hydrochloric acid (1:1 v/v, upper phase). The pigment band was then eluted with methanol-acetic acid (95:5 v/v), concentrated to a few ml. under reduced pressure and further purified by band chromatography using, first, *n*-butanol-acetic acid-water (4:1:5 v/v, upper phase), and, secondly, water-acetic acid (85:15 v/v). The pigment was eluted as before.

The purified pigment was evaporated to dryness *vacuo*, re-dissolved in 2 N hydrochloric acid, heated in boiling water bath for 20 min, then cooled and extracted with iso-amyl alcohol. Purification was achieved by band chromatography on washed sheets of Whatman N 3MM paper, using water-acetic acid-12 N hydrochloric acid (10:30:3 v/v). The acid-treated pigment was eluted as already described. Mineral acid was removed from the pigment-free aqueous solution by washing the solution with chloroform containing 10 per cent di-*n*-octylmethylamine.

The R_F values of the purified pigment were obtained using Whatman No. 1 paper with solvent systems described for anthocyanins⁶, namely, (1) *n*-butanol-2 N hydrochloric acid (1:1 v/v); (2) *n*-butanol-acetic acid-water (4:1:5 v/v); (3) water-12 N hydrochloric acid (97:3 v/v); (4) water-acetic acid-12 N hydrochloric acid (85:15:3 v/v). In addition R_F values of the pigment were determined using the original acidified methanolic extract of fresh galls. With all 4 solvent systems the R_F values of the pigment obtained from the original extract and the purified pigment were similar, showing that there had been no decomposition during the various purification stages. The R_F values of the purified pigment obtained after heating with 2 N hydrochloric acid were determined with reference to a sample of cyanidin chloride using the solvent systems recommended for anthocyanins^{6,7}. These were (1) and (2) as here, (5) formic acid-12 N hydrochloric acid-water (5:2:3 v/v) and (6) water-acetic acid-12 N hydrochloric acid (10:30:3 v/v). Mixtures of the acid-treated pigment and cyanidin chloride were chromatographed in all the given solvent systems and did not form separate spots.

Spectral measurements of the pigment before and after acid treatment were made in the visible region as described by Harborne⁵ using a Unicam S.P. 500. The λ_{max} for the original pigment in methanolic hydrochloric acid was 527 m μ (quoted value for cyanidin-3-monoglucoside 525 m μ ⁸), for the pigment after acid-treatment 535 m μ and for cyanidin chloride 535 m μ . On the addition of 3 drops of a solution of anhydrous aluminium chloride in ethanol (5 per cent, w/v) to the cell solution a shift in the λ_{max} was obtained of 19 m μ for the acid-treated pigment and 18 m μ for cyanidin chloride. This shift shows the compound to have *o*-dihydroxyl groups. The λ_{max} was also determined using as solvent ethanolic hydrochloric acid. The λ_{max} for the unknown and for cyanidin chloride was 545 m μ .

From chromatographic and spectral characters it was concluded that the pigment obtained after acid treatment is cyanidin, this being confirmed by the distribution and oxidation tests, and the tests with the cyanidin and delphinidin reagents, sodium acetate and ferric chloride (Robinson's method⁹).

From the chromatographic data obtained it was concluded that the red pigment of the galls is either cyanidin-3-monoglucoside or cyanidin-3-monogalactoside. The free sugar obtained after acid hydrolysis of the antho-

Table 1. R_F VALUES OF THE PIGMENT FROM *S. fragilis* LEAF GALLS BEFORE AND AFTER ACID TREATMENT

	(1) BuOH/ 2 N HCl (1:1)	(2) BuOH/ AcOH/H ₂ O (4:1:5)	(3) H ₂ O/ 12 N HCl (97:3)	(4) H ₂ O/AcOH 12 N HCl (85:15:3)	(5) Formic acid/ 12 N HCl/H ₂ O (5:2:3)	(6) H ₂ O/AcOH/ 12 N HCl (10:30:3)
Unknown pigment*	0.24	0.37	0.06	0.25	—	—
Unknown pigment after acid treatment	0.70	0.68	—	—	0.21	0.50
Cyanidin chloride	0.69	0.68	—	—	0.22	0.50

R_F values quoted (ref. 6) for cyanidin-3-monoglucoside are: (1) 0.25, (2) 0.38, (3) 0.07, (4) 0.26; and for cyanidin-3-monogalactoside: (1) 0.24, (2) 0.37, (3) 0.07, and (4) 0.26.

nin was investigated by chromatography on Whatman 1 paper using ethyl acetate-water-pyridine (2:2:1), (upper phase), a development time of 26 h, and aniline hydrochloride (Merck) as the locating reagent. The unknown pigment had the same R_F as glucose, and separated from fructose but not from glucose. The same results were obtained when the sugar was chromatographed on thin layers of kieselgel G (Merck) using the solvent system of ethyl acetate-methyl ethyl ketone-methanol-acetic acid (1:1:1 v/v). The spray reagent used was anisaldehyde-sulphuric acid-95 per cent ethanol (5:5:90 v/v), followed by heating at 100° C for 10 min. Glucose and fructose gave a blue colour with the spray reagent, whereas galactose gave a greenish grey, and it was concluded that the sugar obtained from the glycoside was glucose. The latter was confirmed by preparing the osazone which was identical with glucosazone.

The foregoing results, therefore, show that the red pigment in freshly collected galls of *S. fragilis* is cyanidin-3-monoglucoside. The pigment isolated by Nierenstein and Swanton, having been obtained from dried galls, could have been formed during drying and was not the natural pigment.

Isolation of a Lymphoid-cell Protein with Relation to Delayed Hypersensitivity

THE reports on passive transfer of delayed hypersensitivity not only by intact cells but also with cellular extracts¹⁻⁶ have initiated studies regarding the nature of the substance responsible for this effect^{2,4,5,9}. Using free electrophoresis according to Tiselius, it has been shown⁵ that peritoneal-cell extracts from guinea-pigs with delayed hypersensitivity contain a protein fraction moving as the alpha-1 globulins. This protein was absent in extracts from the control animals. With this fraction it was possible to transfer passively the delayed hypersensitivity.

The aim of this investigation was to analyse the protein pattern of lymphoid-cell extracts from guinea-pigs sensitized to 2,4-dinitrochlorobenzene (DNCB) and from normal animals. The main interest was focused on the comparison between the lymph nodes regional to the sensitization and normal lymph nodes, but other lymph nodes from the sensitized animals were also studied.

In the first step of the investigation electrophoresis in starch gel⁷ in a discontinuous buffer system⁸ was used. Ten DNCB-sensitized animals and six control animals provided the material. The experimental set-up was essentially the same as that described below for the disc electrophoresis. By electrophoresis in starch gel it was not possible to discover any differences in the extracts from the different lymph nodes. This is in accordance

with the negative results with human leucocyte extracts separated on cellulose acetate strips⁹.

In the second step disc electrophoresis¹⁰ was employed. Thirty-six white guinea-pigs weighing 300–450 g were used. Sixteen of these served as normal controls, twenty were sensitized epicutaneously with DNCB (20 vol. per cent in acetone, two applications with a 24-h interval). After a test dose of 9 µg DNCB in acetone per square cm all the animals showed positive reactions (erythema and sometimes oedema). The tests were performed on the eleventh day after the first application of DNCB and the animals were killed on the thirteenth day. The lymph nodes were homogenized in a cooled Potter-Elvehjem homogenizer. After freezing-thawing six times the samples were centrifuged in a Beckman Spinco 'Microfuge' for 4 min. The supernatants were mixed with crystals of sucrose to a final concentration of 5 per cent, and could then be used for electrophoresis. This was carried out according to a modification of the disc electrophoresis technique developed in our laboratory. Instead of using a large-pore gel of 2.5 per cent polyacrylamide on top of the column, an anticonvection medium consisting of 'Sephadex G-200' sedimented in 20 per cent sucrose was used and mixed with the sample. The electrophoretic procedure is shown schematically in Fig. 1. Electrophoresis was first carried out in gels of 7.5 per cent concentration for 30 min at 3.3 m.a.p. Sections were cut out of the gels and transferred to the top of a column 6.8 mm wide containing 7.5 per cent gel and carefully homogenized with a glass rod. The end of the column was covered with a 'Visking 18/32' cellulose membrane. Thus there was a little space of about 300 µl. between the lower end of the gel and the membrane, which, after electrophoresis for 2 h at about 3 m.a.p. contained the non-dialysable proteins from the gel sections originally placed on the column. This specimen could be additionally concentrated about three-fold by stirring dry 'Sephadex G-25' into the solution until a thick suspension was obtained. The gel grains were removed by centrifugation. The supernatant was mixed with sucrose and layered above a 6.8 × 40 mm column containing 15 per cent polyacrylamide gel. Even this column was charged with an anticonvection medium of 'Sephadex G-200'. Electrophoresis was carried out using a current of 3.0 m.a.p. for 100 min. Staining was performed in 0.1 g per cent amido black in 7 per cent acetic acid.

In the first electrophoretic run (7.5 per cent gel) fifteen bands were separated in extracts from lymph nodes of whatever sort. However, the band corresponding to albumin in extracts from the nodes regional to the sensitization appeared to be more concentrated than that of the control nodes. This band was further resolved in the run in the 15 per cent gel; in samples from the hypersensitive animals four distinct bands appeared compared

Fig. 1

Fig. 2. Pherogram of lymph node extract from a normal animal (left) and a DNCB-sensitized animal (right). Two fast-moving components are visible ahead of the albumin (strong band) in both extracts from normal and DNCB-sensitized animals; the latter show a specific fraction with an electrophoretic mobility lower than that of albumin.

with three bands from the control animals (Fig. 2). It was also possible to visualize the fourth band by electrophoresis in 15 per cent gel at once without the preceding runs in 7.5 per cent gel. However, the separation was not very good in this case. The pre-albumins, also separated, have been shown to vary a little between the animals, possibly due to genetic differences.

In this investigation extracts from lymph node cells regional to the place of sensitization were used. A very weak fourth band was also found in extracts from the lymph nodes regional to the test place, while in extracts from the neck lymph nodes of the same animal this band was barely discernible. In other experiments we recently have found that the fourth band seems to be present at the highest concentration about a fortnight after sensitization. This coincides with the maximum lymphocyte infiltration in the epidermis of the test area¹¹. To exclude a possible effect of the small quantity of serum left in the nodes, the sera from the animals were also separated using both the electrophoretic methods. No differences between normal and sensitized animals were seen.

We thank Prof. Ove Groth, who kindly supplied some of the sensitized animals.

Note added in proof. During the course of publication the protein fraction described here has been further analysed and found to be an IgA (= beta-2A) globulin.

The investigation was supported by the Swedish Medical Research Council.

Formation of Complexes between Basic Proteins of Leucocytes and Plasma Globulin

RECENT studies have shown that cationic proteins from leucocytes produce tissue injury and responses characteristic of immunological reactions¹⁻⁴. In an earlier publication we put forward the hypothesis that homograft rejection may be caused by such cationic proteins⁵. The specificity of the homograft reaction could only occur if the basic protein were transported to the homograft site via specific antibody (globulin) or in cells which have specificity through some chemotactic response of the cells to antigen.

This report presents a new technique in disc electrophoresis for the purpose of demonstrating the formation of a complex between basic proteins and purified globulin of serum. The method is a general one which may be applied to other complexes, but is described below from the standpoint of complexes involving plasma globulin.

The technique combines the standard system of disc electrophoresis⁶ which resolves anionic proteins with a reversed system⁷ that resolves cationic proteins. Resolution in the first system frees the complex (anionic) from any uncomplexed cationic component. The total protein migrating in this system is then transferred, in its gel, the sample layer of the reversed system. Depending on the pH of the second or reversed system and the stability of the complex at that pH, resolution will show the cationic component of the complex. Any such protein appearing at this final stage must have been brought into the lower gel of the original sample tube on a 'carrier', complexed with a globular protein.

The pH of the sample gel as well as the 'running pH' of the first system must be those at which the complex is stable, whereas the same pH values in the second system would be those at which the complex is split into its components. These considerations led to a modification of the standard disc electrophoresis system regarding the pH of the various gels employed. This system normally resolves anionic substances having free electrophoretic mobilities in the range -0.6 to -7.5. The new system is specifically designed to give the greatest resolving power in the mobility range -0.75 to -1.0 which includes the slow α -, slow β -, and γ -globulins. The pH of the sample gel has been raised from a slightly acid pH of 6.9 to a pH of 7.5 which closely approximates to that of whole blood. The pH at which electrophoresis actually occurs is reduced from 9.5 to 8.6, thus maintaining a mildly alkaline medium for the sample at all times.

The changes made are only in the amounts of *tris* employed in the upper gel, lower gel and buffer. The new values for 100 ml. of solutions A (pH 7.2), and B (pH 7.3) are 10.65 g and 6.0 g, respectively, and the buffer quantity for 1 l. is changed from 6.0 g to 10.0 g (pH 8.5). All other solutions as well as techniques for gel formation and processing are as adopted at present. Because of the selectivity of this system for molecules of high molecular weight, it is recommended that gel concentration of 15 per cent and higher be used to effect the greatest possible resolutions.

In practice, the technique is carried out as follows. The two components of the complex to be tested are allowed to conjugate and they are then polymerized into the sample gel of the first system. No indicator dye is used because of the possible combination of the dye with one of the constituents of the complex. The ionic boundary is identified during the run by noting the difference in the refractive index between the upper and lower solutions. When the eye is placed on the level of this front it can be plainly seen. The ionic front is allowed to migrate into the lower gel only a short distance. The lower gel containing the protein is removed from the glass tube and the upper portion, containing the sample, is cut off with a sharp knife. This gel is then transferred, with the same orientation (not inverted), to the sample layer of a tube made up in the reverse system. It is covered with

Fig. 1. Acrylamide-gel disc electrophoretic separation of basic (cationic) protein (B) from the carrier, α -globulin (G). The orientation of migration is shown on the left side of the gel.

upper gel solution, all trapped air bubbles removed and then polymerized into the tube. When the ionic boundary has entered the lower gel, the hard sample gel may be removed using a bent syringe needle or hook. The boundary is allowed to migrate a previously measured distance, the gel removed from the tube, stained and de-stained in the usual manner.

Fig. 1 shows the separation of basic protein (B) carried as a complex with α -globulin fraction (G) by the technique described above. The basic protein was isolated from polymorphonuclear leucocytes of rabbits using the method of Cohn and Hirsch⁸. The α -globulin was obtained commercially from International Chemical and Nuclear Corporation, City of Industry, California. The purity of this material was checked by disc electrophoresis prior to use.

Similar experiments were conducted in which protamine was substituted for the basic protein of the leucocyte. No protamine complexed with the α -globulin in the technique previously described.

The results of these experiments clearly demonstrate the transporting of basic (cationic) proteins from polymorphonuclear leucocytes on globulin molecules. These observations become extremely provocative in the light of other work which has demonstrated that basic protein from a similar source has bactericidal activity² and also provokes inflammatory-like reactions¹. Such complexes would facilitate an accumulation of toxic substance at the site of antigen-antibody interaction.

A question immediately arises whether the complex of the cationic protein and globulin remains after the globulin reacts with antigen of foreign tissue. Experiments are under way to determine the toxicity of the complex versus the free basic protein.

A possible mechanism by which one might get dissociation of such complexes would be through discharge of electrostatic attraction at the time of globulin-antigen combination. An alternative method for the dissociation could be proposed if one assumes that the low molecular weight basic protein exists as a helix. Helical configurations have been shown in various peptide chains⁹⁻¹¹. Cohn and Hirsch have shown that the basic proteins exist as granules in polymorphonuclear cells and are released whenever the cell pH drops to approximately five¹². Granule release at such a pH might occur if the protein configuration changed from a helix to a random coil.

The formation of a random coil might present such spatial differences that the globulin-cationic protein com-

plex would dissociate. Since no complex with protamine could be demonstrated, structural differences could be assumed to have importance and not simply the basicity of the molecule.

We have already shown that removal of basic proteins from the peritoneal cavity with a Millipore 'trap' increases homograft survival⁵.

This research was supported in part by U.S. Public Health Service grants AM 06020 and CA 05813, National Institute of Arthritis and Metabolic Diseases.

Note added in proof. Since submitting this article for publication, additional experimental details covering the electrophoresis of ionic complexes have appeared¹³.

PHYSIOLOGY

Effect of Altered Perfusion Rates on the Retention of Noradrenaline by the Spleen

In the majority of investigations concerning the mechanism of retention of circulating noradrenaline by tissues, the amine has been administered by intravenous injection. Noradrenaline itself, as well as a wide variety of physiological and pathological conditions, are known to exert profound effects on the flow of blood through tissues. It is important, therefore, to establish the effect of changes in flow rate on the uptake of circulating noradrenaline or that liberated by sympathetic nerve stimulation. The evidence in the literature on this point is conflicting. It has been shown that the greater the flow of blood through the organ, the greater is the amount of noradrenaline in the venous effluent following stimulation of the post-ganglionic sympathetic nerves to spleen¹⁻³, intestine⁴ and skeletal muscle⁵. On the other hand, spontaneous changes in flow rate have been reported to be without effect on the retention of noradrenaline by the perfused heart⁶ and the perfused spleen⁷. Consequently, we have examined the effect of different, controlled flow rates on the uptake of tritiated noradrenaline by the perfused spleen.

Spleens of cats were perfused by means of a technique similar to that recently described by Fischer *et al.*⁸. However, the procedure differed in the following respects: the intestines were left intact while both the left gastric and hepatic arteries were ligated and the coeliac artery was cannulated. The spleen was perfused, at a constant flow rate, with oxygenated Krebs solution at 37° C, by means of a 'Sigmamotor' pump (model TM11). Perfusion pressure distal to the pump was monitored continuously using a Statham P-23A pressure transducer, the output of which was displayed on a Grass model 5 polygraph. The spleen was kept warm with cotton pads soaked in mineral oil at 37° C. The splenic nerves were cut immediately prior to the infusion of tritiated noradrenaline. Chromatographically pure tritiated *dl*-noradrenaline as a solution of the hydrochloride (New England Nuclear Corp.), with a specific activity of 7.6 c./mmole, was infused into the tubing leading to the perfusion pump using a Harvard infusion pump (model 500-910). The rate of infusion of

the amine was such as to ensure that the concentration of tritiated noradrenaline was 4.8 mg/ml. regardless of the flow rate. At each flow rate used, a total of 50 ng tritiated noradrenaline base was infused. Each spleen was perfused at least three times with the labelled amine, the first and last perfusion always being at the same flow rate. The venous effluent was collected for 2 min before, during and for 15 min after the infusion of tritiated noradrenaline, each sample being collected for 1 min. To each sample, one-tenth of the volume of 4 M perchloric acid was added. Fifteen minutes later the samples were centrifuged in a clinical centrifuge. In each case, the supernatant fluid was decanted, its volume measured, and a 0.1-ml. aliquot mixed with 10 ml. Bray's phosphor. The total radioactivity of the aliquot (^3H -total) was then determined in a Packard 'Tri-carb' liquid scintillation spectrometer having an efficiency for tritium of 25 per cent. Quenching was determined by the internal standard method using tritiated water. Results are corrected for quenching, which ranged from 20 to 25 per cent. Retention of tritiated noradrenaline was taken as the difference between the total amount of tritiated noradrenaline infused (assessed by direct measurement of tritium) and the total amount of tritium recovered in the venous effluent during and for 15 min after the infusion. At least 75 per cent of the tritium recovered was found in the venous effluent within 6 min of terminating the infusion.

The results of these experiments are shown in Table 1. The amounts of tritiated noradrenaline retained in the spleen during the first and last perfusions at the same flow rate were very similar. With increasing flow rates significantly decreased amounts of total- ^3H were retained by the spleen.

At the concentration used in this investigation the retention of noradrenaline would be dependent mainly on a saturable membrane transport mechanism⁹⁻¹². When the noradrenaline concentration is constant, such a process would be expected to operate at a constant rate⁹⁻¹². It follows, therefore, that when the noradrenaline was infused, its passage across the membrane should proceed at the same rate regardless of flow through the organ. In our investigation, the only experimental variable was the flow rate, alterations of which necessitated increasing or decreasing the total time during which the noradrenaline was added to the perfusion fluid. The durations of noradrenaline infusion at the different flow rates are given in Table 1. Table 1 shows that there was an inverse relationship between total retention of tritiated noradrenaline and flow rate. This finding shows that retention of noradrenaline by tissues is a function of the duration of the time during which the amine is in contact with the uptake sites. After the completion of our investigations the results of a single experiment with similar results was reported¹³.

If the transport and/or diffusion mechanism operates at a constant rate, then the retention of amine per unit time should be the same regardless of blood flow provided that the concentration is fixed. When the data of Table 1 were used to calculate the fraction of the total noradrenaline retention that took place per minute (that is, the rate of retention), the relationship shown in Table 2 resulted. This reveals an apparent increase in the rate of retention with increasing flow rate. If retention, in fact, takes place at a constant rate, it may be that the higher flow rates caused the apparent increase in the rate of retention (Table 2) by virtue of their perfusing more of

Table 2. PERCENTAGE OF TRITIATED NORADRENALINE RETAINED IN THE SPLEEN PER MIN AT DIFFERENT FLOW RATES

Flow rate (ml./min)	Mean tritiated noradrenaline retained (percentage/min)
3.5	13.7
7.0	18.7
14.0	28.7

the splenic tissue, thus bringing the tritiated noradrenaline into contact with more sites at which its retention can take place. Perfusion pressure was only slightly elevated by increasing the flow rate from 3.5 to 14 ml./min.

This investigation directs attention to the importance of fluid flow rate as a determinant of noradrenaline retention by tissues. Altered flow rates change the time available for retention of noradrenaline by binding sites as well as the extent of functional tissue perfusion. A practical implication of this work is that a single, rapid injection of noradrenaline, by altering the blood (or perfusion fluid) flow through a tissue, may thus influence the magnitude of retention. Slow infusion of the amine would circumvent this hazard. It has also been shown that the fraction of the cardiac output delivered to an organ is another determinant of noradrenaline retention.

Role of Portal Blood Supply in Liver Regeneration

It has been known for many years that in laboratory animals, such as the rat, partial hepatectomy is followed by liver regeneration. In recent years it has been generally accepted that this response is initiated by some sort of humoral mechanism¹. This view was, however, originally based on parabiotic and serum injection experiments the validity of which has been contested. We have therefore been led to re-examine the alternative and much older 'blood-flow' theory². This postulates that after partial hepatectomy the remaining liver fragment acquires a much more generous blood supply, since it has to accommodate portal vein blood previously destined for the excised lobes. It is this over-generous blood supply which is said to act as the stimulus to hyperplasia. The strongest evidence in favour of this theory was derived from experiments on domestic fowls, by taking advantage of the anastomosis between the post-caval and

Table 1. PERCENTAGE OF INJECTED TRITIATED NORADRENALINE RETAINED IN THE SPLEEN AT DIFFERENT FLOW RATES

Weighted \pm test¹⁵: (a) versus (b), $P < 0.001$; (a) versus (c), $P < 0.01$.

portal veins through the coccygeo-mesenteric vein. It is therefore possible to increase portal blood flow by simple ligation of the postcaval vein between the kidneys and the liver. According to the 'blood-flow' theory this should itself cause hyperplasia of the liver. Furthermore, the 'blood-flow' theory would predict that, in the fowl, partial hepatectomy would not be followed by liver regeneration, since the blood which would normally be accommodated by the missing lobes could instead return to the heart via the anastomosis. It was claimed that both these theoretical predictions were fulfilled experimentally¹, since the number of fowls used in these original experiments was small, and since the criteria of liver growth were very crude, it seemed worthwhile to repeat them in an improved form using mitotic frequency as an index of liver growth. For this purpose we have used 26-week-old pullets of the "Sussex Legbar" strain weighing about 200 g. For both operations the fowls were anaesthetized lightly with intravenous 'Nembutal', and anaesthesia completed with ether. In the partial hepatectomy the entire left lobe of the liver was removed through an incision on the left side parallel to the edge of the sternum and 1 cm above it. Ligation of the postcaval vein was performed through an incision in the right flank⁴.

Table 1 shows the effect of partial hepatectomy. Before the operation the mitotic frequency is very low—less than 20 per 100,000 nuclei. After the operation it shows a rather irregular increase for the first 3 or 4 days and then appears to return to a figure not very different from the pre-operative level. This suggests that, contrary to the blood flow theory, there has been a regenerative response of a sort; admittedly less dramatic than that seen in the rat, but it must be remembered that only 40 per cent of the fowl liver was removed compared with 60–70 per cent removed in most rat experiments. Table 2 shows the effect of ligation of the postcaval vein, as compared with that of a sham operation. Both procedures give mitotic frequencies rather higher than the pre-operative figures shown in Table 1; but there is no indication that the ligation has any more effect than the sham operation. This result also is in flat contradiction to the 'blood flow' theory.

Taken together, the results shown in Tables 1 and 2 seem to deprive the 'blood flow' theory of its one apparently secure experimental support. It seemed, however, desirable to carry out an analogous series of experiments in some species which, unlike the fowl, is known to show the classical regenerative response to partial hepatectomy. We have therefore compared the effects in the dog of partial hepatectomy⁵ and of the establishment of a reverse Eck fistula⁶. The latter procedure, by increasing the blood flow through the liver, would be expected, according to the 'blood flow' theory, to cause liver growth similar to that which follows partial hepatectomy. The results are shown in Table 3. Partial hepatectomy, as expected, produced a very large increase in mitotic activity demon-

* Biopsy from left lobe (see text).

strable 3, 6 and 9 days after the operation. By contrast, establishment of the shunt in general produced no significant increase over the pre-shunt level. There was, however, one exception. In general, when the animals were under anaesthesia before being killed, the livers were a dark bluish colour, they appeared turgid, and the normally sharp edges of their lobes had become rounded and the surface often presented a fine nutmeg appearance. At death, the liver of animal number 6, though showing the usual rounding of the sharp edges, did not have the usual homogeneous dark colour. The left central and left lateral lobes were a bright red in contrast to the bluish colour of the rest of the liver. This colour difference disappeared after death when the liver was excised. The mitotic index in the red lobes was extremely high and of the order of that seen following partial hepatectomy (Table 3). In the rest of the liver it remained at the pre-shunt level. This anomalous result can most easily be explained on the assumption that in some unknown fashion the reverse Eck fistula had disturbed the haemodynamics of the liver in such a way that blood being delivered to the left lobes was better oxygenated than that being delivered to the right. The high mitotic frequency observed in the left lobes might well be attributable to a relative increase in the oxygen saturation of its blood supply. However that may be, it seems quite clear from Table 3 that increased blood flow does not by itself bring about growth of liver tissue.

The blood flow theory of liver regeneration would therefore seem to be untenable, at least in the form in which it was originally stated.

Chemotopic Organization in the Bulbar Gustatory Relay of the Rat

In the relay nuclei of the mammalian auditory system, one representation of sound frequency is the location of maximum neural activity within a nucleus. This spatial representation of stimulus quality is called tonotopic organization¹. In the gustatory system, change in the response magnitudes to chemicals as a function of change in tongue region stimulated has already been demonstrated in the nucleus of the fasciculus solitarius (NFS)². The preliminary data to be presented here indicate that discrete sub-areas which are highly responsive to some chemicals are located in the anterior tongue zone of the bulbar gustatory relay of the rat. The recording and stimulating techniques have been described previously^{2,3}.

The active electrode was a nickel-chrome wire, 25-4 μ in diameter, insulated except at the tip. The multi-unit neural activity was led through an electronic summator⁴ into a recording milliammeter. The stimuli were liquids which flowed over the anterior tongue through a tongue chamber.

In the first experiments, neural responses were recorded at two depths along a single vertical electrode track in the bulbar gustatory relay. The order of response magnitudes at the more dorsal recording loci was: 0.1 M NaCl > 0.005 M HCl > 0.1 M KCl > 0.01 M NaCl > 0.01 M quinine hydrochloride (QHCl) = 0.1 M sucrose. In contrast, at the more ventral loci, the order was: 0.1 M NaCl > 0.005 M HCl > 0.1 M sucrose > 0.1 M KCl > 0.01 M NaCl > 0.01 M QHCl (summed ranks from seven animals). Note that sucrose moved from least effective at the more dorsal loci to two from the top at the more ventral loci. These different orders of stimulus effectiveness were each, for the seven animals used, statistically consistent: dorsal, $W = 0.35$, $P < 0.05$; ventral, $W = 0.61$, $P < 0.01$ (Kendall's W , ref. 5). However, the differences between the magnitudes of the more dorsal and the more ventral responses (taken relative to 0.1 M NaCl at each depth) were significant only for sucrose and for QHCl (Fig. 1) ($P < 0.05$, Wilcoxin signed rank (WSR), ref. 5). The more ventral sucrose response was larger in all but one animal; the QHCl response was smaller in all but one. The bulbar surface co-ordinates for the electrode tracks in these animals correspond to the location of the NFS.

The two-depth responses were next studied, using a range of sucrose concentrations. Fig. 2 shows that the absolute magnitudes of the more ventral sucrose responses were larger than those of the more dorsal responses ($P = 0.025$, WSR, ref. 5). Therefore, the previously

Fig. 1. Median summated relative response magnitude (response to 0.1 M NaCl at each depth, 100) at two electrode depths along a single vertical puncture in the bulbar gustatory relay. Median separation: 50 μ based on seven rats. Anterior tongue stimulated by each of the five chemicals shown, and by the 0.1 M NaCl reference standard

Fig. 2. Absolute response magnitudes recorded at two depths along a single electrode track to sucrose solution stimulation of the anterior tongue. Done in three animals (not those included in Fig. 1), median values shown. Separation between recording depths: 50 μ (median). The brain of one rat studied histologically. The electrode track marking the responsive area ended in the nucleus of the fasciculus solitarius

Fig. 3. Photograph of summated multi-unit responses recorded in the medulla oblongata of one rat. Records taken at 1.20 mm, 1.21 mm, and 1.22 mm ventral to the dorsal surface of the medulla. Heavy vertical time lines are 20 sec apart. Deflexion in signal marker below each record indicates approximate onset and duration of flow of each liquid. Tongue chamber empty of liquids except during stimulus flow. Records read from left to right. Critically damped, rectilinear recording milliammeter. An electrolytic lesion which was made in the responsive area was found in the nucleus of the fasciculus solitarius of the myelin stained brain. The response to sucrose is seen to double relative to NaCl; to triple, in absolute magnitude

observed increase in sucrose responsiveness with depth was not actually a decrease in responsiveness to the other stimuli. Further, the relative response magnitudes (re: 0.1 M NaCl at each depth) for the wide range of sucrose concentrations were significantly larger at the more ventral loci ($P < 0.01$, WSR, ref. 5), thus demonstrating that the increase is not just a rise in the response magnitudes to all chemicals. Thus, responsiveness to sucrose increased at deeper recording sites in the bulbar gustatory relay, while responsiveness to QHCl decreased at the deeper sites.

When the recording electrode was driven through NFS in small steps, it was observed that, with an increase in electrode depth of only 20 μ , the response magnitude to 0.1 M sucrose often enlarged considerably, both relative to 0.1 M NaCl and in absolute response magnitude (Fig. 3). In order to examine the highly responsive regions more closely, additional experiments were made. The electrode was driven through NFS in steps of either 20 or 25 μ , and several stimuli were applied to the tongue at each step. Two patterns of response versus depth were observed (Fig. 4): a superficial, narrow area within which QHCl gave large responses, while no large responses to sucrose were recorded anywhere along the electrode track (Type A); and a deep, narrow area in which sucrose gave large responses, while nowhere along the track did QHCl give large responses (Type B). In two other animals, the response magnitudes to sucrose and QHCl were both large, separated by ≤ 21 per cent points. The highly responsive areas were narrow. In one of these animals, the maxima occurred at the same depth, half-way through the responsive area (50 per cent of total depth). In the other animal, the QHCl maximum was quite superficial; the sucrose maximum, deeper. An analysis of variance was applied to the maximum response magnitudes of the A- and B-pattern animals, as well as to those animals whose maxima differed by ≤ 21 per cent points. The analysis indicated that the responses differed significantly for both sucrose ($P < 0.008$) and for QHCl ($P = 0.05$; Kruskal-Wallis⁵).

It is unlikely that the sub-areas observed are highly responsive only to sucrose or only to QHCl. However, glucose and maltose did not yield large responses in 'sucrose' sub-areas, while quinine sulphate, sucrose octa acetate, and caffeine (all bitter)⁶ produced only small responses in a 'QHCl' sub-area. Thus, although indications of a chemotopic organization have been observed, the defining chemical characteristics, and many other factors, remain to be determined.

Fig. 4. Median summated response magnitudes to 0.05 M NaCl, 0.02 M quinine hydrochloride (QHCl) and 0.1 M sucrose, recorded in the nucleus of the fasciculus solitarius. Response magnitudes are expressed as percentages of the maximal response of each rat to 0.05 M NaCl. The distance from the beginning (dorsal limit) to the end (ventral limit) of the responsive area was converted into percentages (median size was 380 μ). An electrolytic marker lesion was made at the recording site in each animal, and located in the anterior tongue zone of the nucleus of the fasciculus solitarius. A. Animals (N, 3) which had (1) a maximum response to QHCl ≥ 60 per cent; (2) a maximum response to sucrose ≤ 30 per cent; (3) a separation of at least 38 per cent points between QHCl and sucrose responses. B. Animals (N, 2) which had (1) a maximum sucrose response ≥ 50 per cent; (2) a maximum QHCl response ≤ 39 per cent, and (3) a sucrose-QHCl response difference of at least 25 per cent points.

Evidence for a Poisson Distribution of Miniature End-plate Potentials and some Implications

MINIATURE end-plate potentials (m.e.p.p.s), first discovered at the frog neuromuscular junction, have now been detected at mammalian, avian, piscine, crustacean, and insect neuromuscular junctions, at frog and chick ganglionic synapses and at frog and cat spinal cord synapses¹.

Invariably the spontaneous release of transmitter has been shown to occur at random intervals indicating no interaction between consecutive potentials. It is surprising, therefore, that the next step in such an analysis—the determination of the statistical distribution best suited to the description of the m.e.p.p. frequency—appears not to have been undertaken, particularly in view of the fact that it is generally believed that an end-plate potential represents a momentary acceleration of m.e.p.p.s, and the number of quanta in each e.p.p. evoked by nerve stimulation is distributed according to a Poisson distribution². It seemed worthwhile, therefore, to determine whether the spontaneous release of quanta recorded as m.e.p.p.s also fits such a distribution. This was done in rat hemidiaphragm-phrenic nerve preparations *in vitro*. The method of dissection, the mounting of the preparation, and the bathing solution have been previously described³. M.e.p.p.s were recorded with microelectrodes filled with 3 M potassium chloride and frequencies were counted from photographed oscilloscope sweeps. Eight series of m.e.p.p.s were analysed (Table 1). In each, the mean frequency (m) per unit time interval (usually corresponding to one oscilloscope sweep) was calculated. The probability of finding sweeps containing $k=0, 1, 2 \dots n$ m.e.p.p.s was derived from the Poisson formula $p(k) = e^{-m} \frac{m^k}{k!}$. The closeness of fit between the theoretical ($N_p(k, m)$) and observed frequencies (N_k) was determined by use of the χ^2 test with $n-2$ degrees of freedom (where n = the number of comparisons of k). The expected number of intervals for any k was usually kept greater than 5 by grouping k 's. The column 'total N ' shows the total number of m.e.p.p.s observed in each series. The last column in Table 1 (χ^2 level per cent) indicates the approximate percentage of ideal cases in which chance fluctuations would give a worse agreement between observation and theory.

In the first three experiments shown in Table 1, m.e.p.p.s were recorded from neuromuscular junctions in control solution. It is clear that the distribution of m.e.p.p.s in all three trials closely fitted a Poisson. At first sight, the type of distribution may appear to be of little importance, but the demonstration of a Poisson distribution has some important implications. First, it is consistent with the hypothesis that the e.p.p. is the result of synchronization of m.e.p.p.s; that is, quanta which would normally be released in periods of 50 or more sec are released in less than a millisecond under the influence of the presynaptic spike. Secondly, if it is assumed that quanta are reformed in presynaptic terminals (vesicle hypothesis), and that the probability of release is determined by the probability of collision of these quanta with the presynaptic membrane⁴, then some interesting conclusions can be drawn from the fact that the spontaneous release of quanta conforms to a Poisson distribution. The release of each m.e.p.p. must be independent of past or future events, that is, the release of quanta cannot have influenced the probability of release of quanta remaining in the terminal. This implies that the population of releasable quanta remained constant, despite losses. This could occur in many ways; the lost quanta may be very rapidly replaced, or the population of releasable quanta may be so large that those lost cause little alteration of the release probability and are slowly replaced.

When the release rate of quanta was increased to 50/sec by raising the potassium concentration to 10 mM (exp. 7, Table 1), the distribution of m.e.p.p.s was still highly consistent with the Poisson hypothesis (χ^2 level 85 per cent). It has been suggested that the deviation of e.p.p. amplitude from a Poisson distribution when the quantal content of e.p.p.s is high (50–200) may be caused to some extent by an increase in the probability of release of remaining quanta⁵. It was afterwards shown that a better fit to a Poisson distribution could be obtained by

using a compensating factor for the non-linear summation of quanta⁶. The present results show that quantal release rates of 50/sec cause no change from a Poisson distribution of quantal release and indicate, in terms of the hypothesis of preformed quanta, that adequate refilling of the store must occur to maintain constant parameters for the Poisson.

In exp. 8, Table 1, the drug hemicholinium No. 3 (α - α -dimethylethanolamine 4,4'-biacetophenone, HC3) was used at a concentration of 4×10^{-6} M to inhibit ACh synthesis^{7,8}. An attempt was then made to deplete the transmitter store in magnesium-blocked preparations by stimulating the phrenic nerve at a rate of 12/sec. Under these conditions, both e.p.p.s and m.e.p.p.s could be observed, and the quantal content of the e.p.p.s remained at approximately 10 throughout the experiment. After 45 min, when e.p.p. and m.e.p.p. amplitudes had decreased 60 per cent, which presumably corresponded to a similar reduction in the store of transmitter⁸, the series of m.e.p.p.s shown in experiment 8 was analysed. It is evident that there is a remarkably good fit to a Poisson distribution in spite of the depletion of ACh. This result suggests that the population of releasable quanta remained approximately constant so that each quantum might be expected to contain less ACh, and in fact it was observed that m.e.p.p.s had become smaller in amplitude.

An alternative hypothesis⁵, which fits these observations and does not depend on the postulate of preformed quanta, cannot be ignored. The probability of transmitter release may depend on the random activation of a small fraction of a large population of potential release sites in the presynaptic membrane. On the assumption that the probability of activation of potential release sites is a function of the extracellular calcium concentration⁹, several series of e.p.p.s in solutions containing varying calcium concentrations were examined. In expts. 4, 5 and 6, Table 1, the calcium concentrations of the bathing solutions were 0, 9 and 16 mM respectively, but all three series were again in excellent agreement with the Poisson predictions. In several experiments with 16 mM calcium chloride, however, the χ^2 level appeared to be less than with the normal concentration of calcium chloride (2 mM). At present it is difficult to think of decisive experiments

to differentiate between the two hypotheses. It has been shown that quantal size does not fall during depletion of the transmitter store during a tetanus, yet the reduced e.p.p. amplitudes still conform to a Poisson distribution¹⁰. In terms of the vesicle hypothesis, the reduction of quantal content implies that the store of quanta was reduced and consequently one might have expected some deviation from a Poisson distribution. The second of the two hypotheses described is more consistent with these observations.

The experiments presented demonstrate that the conformity of spontaneous transmitter release to a Poisson distribution is very significant under a variety of experimental conditions which might have been expected to affect the probability of release and thus cause deviations from this distribution. The very persistence of this conformity to a Poisson distribution must provide a powerful test of the various hypotheses of transmitter release.

PHARMACOLOGY

Anticoccidial Activity of Nicotinamide Antagonists

THE life-cycle of poultry coccidia can be inhibited by certain *p*-aminobenzoic acid¹⁻³, folic acid³⁻⁶ and thiamine⁷ antagonists. This knowledge led to our testing three known antagonists of another vitamin, nicotinamide, for anticoccidial activity. These substances were 3-acetylpyridine⁸, pyridine-3-sulphonamide⁹ and 6-aminonicotinamide¹⁰.

To evaluate the activity of the compounds, they were mixed in chick starter mash of known composition and fed to one-week-old cockerels, starting one day before they were inoculated orally with approximately 200,000 sporulated oocysts of *Eimeria tenella* or *E. necatrix*, or 1,000 sporulated oocysts of *E. acervulina*. In each test one infected and one uninfected control group of birds were fed unmedicated ration. The criteria to assess activity were a comparison of mortality and oocyst reduction¹¹. The toxicity of the compounds was assessed in both infected and uninfected groups by a comparison of death rates and weight gains of the birds individually weighed at intervals.

3-Acetylpyridine at 0.1 per cent w/w in the food was inactive against both *E. tenella* and *E. acervulina*.

Pyridine-3-sulphonamide at 0.025 per cent w/w was inactive against *E. tenella* and *E. necatrix*, and showed no signs of toxicity when fed for eight days. It was active against *E. acervulina*, but less effective than sulphaquinoxaline, the reference compound (Table 1). The results of exp. 3 indicate the possibility of different strain responses. The activity was neutralized by simultaneous feeding of an equal concentration of nicotinamide (exps. 4 and 5, Table 1). In another single experiment the activity of pyridine-3-sulphonamide was not antagonized by equal concentrations of *p*-, *o*- or *m*-aminobenzoic acid.

6-Aminonicotinamide showed a different spectrum of activity to pyridine-3-sulphonamide. It was active against *E. tenella* at low concentrations comparable with those of the control drug amprolium (1-(4-amino-2-n-

Results of three experiments added together. Groups balanced for weight at the start of each test.

* As Tables 1 and 2.

propyl-5-pyrimidinylmethyl)-2-picolinium chloride hydrochloride) (Table 2), but there was little margin between the active and toxic concentrations. This nicotinamide analogue was active against *E. necatrix* and inactive against *E. acervulina* at the maximum tolerated concentration. Lower concentrations were not examined against *E. necatrix*.

The results in Table 3 show that one-half to twice the concentration of nicotinamide added to 6-aminonicotinamide has some effect in offsetting its toxicity as judged by the deaths and depression of gain in weight; but four times or more the amount of the vitamin was required to neutralize the anticoccidial activity and toxicity of this analogue.

These observations suggest that nicotinamide is a growth factor for *E. tenella*, *E. acervulina* and presumably for *E. necatrix*.

It is interesting to note that pyridine-3-sulphonamide showed activity only against *E. acervulina*, which is also generally more sensitive than *E. tenella* and *E. necatrix* to sulphanilamide derivatives. This may indicate that for *E. acervulina* transport of drugs to the site of action is enhanced by a weakly acidic group such as $-\text{SO}_2\text{NHR}$.

PATHOLOGY

Induction of Malignant Lymphomas by Urethane in Adult Mice bearing Syngeneic Thymus Grafts

In recent years it has repeatedly been proved that neonatal or very young animals are very susceptible to carcinogenesis induced by different agents. One possible explanation is that tissues of new-born animals contain a large number of incompletely differentiated cells, particularly responsive to carcinogenic stimuli. It is relevant to this speculation that a close correlation has been noted between susceptibility of mice to develop malignant lymphomas and the presence in the thymus of a great concentration of immature cells, whether by reason of early age¹, genetic constitution², whole-body X-irradiation³, or regenerative changes in implanted thymus⁴. In thymectomized, virus-inoculated⁵ or X-irradiated⁶ mice, implantation of new-born thymus proved much more effective than adult thymus in restoring leukaemogenesis.

Previous work showed that urethane (ethyl carbamate) in adult mice was practically devoid of leukaemogenic activity^{6,7}, although effective in inducing thymic changes⁸. On the other hand, administration of this chemical to new-born animals was found to provoke a significant number of malignant lymphomas⁹. Urethane-induced lymphomas originated in nearly all cases in the thymus, only later acquiring the character of a generalized disease.

The experiments reported here were undertaken to investigate whether, by making use of single or multiple grafts of new-born thymus as a more suitable target tissue, adult mice would be rendered susceptible to the leukaemogenic action of urethane.

C57BL male mice aged 2-3 months were grafted subcutaneously into the right flank with one or five thymuses obtained from 1- to 5-day-old syngeneic donors. Starting 5 days after implantation, they received urethane in drinking water at the 0.3 per cent level for 30 days, continuously. Adult C57BL mice of both sexes treated only with urethane served as controls. The total quantity of the chemical administered to animals of the different groups amounted to an average of 220 mg per mouse. A certain number of mice died within 30 days from the end of treatment, presumably owing to the toxic effect of urethane. They were not included in the investigation.

Table 1. MALIGNANT LYMPHOMAS INDUCED BY URETHANE IN C57BL MICE IMPLANTED WITH SYNGENEIC SINGLE OR MULTIPLE THYMUSES

Thymus graft	No. of mice in group	Mice with lymphomas No.	%
None	44	1	2
1 thymus	15	2	13
5 thymuses	22	9	41

The results, which refer to an 8-month period of observation from the end of urethane administration, are summarized in Table 1. It is evident that the highest incidence of malignant lymphomas occurred in the group grafted with 5 thymuses (41 per cent), while in animals receiving only a single thymus the incidence was markedly lower (13 per cent). However, only in the case of multiple grafts was the incidence statistically significant in comparison with the control group ($\chi^2 = 14.15$; $0.001 < P < 0.01$). Neoplastic disease in all thymus-implanted animals was initiated after a mean latent period of four months as a localized growth at the graft site, and reached a maximum diameter of 40-50 mm in about 40 days (Fig. 1). Generalized leukaemia appeared later, except in three animals implanted with 5 thymuses, which at death had only local tumours. *In situ* thymus of leukaemic mice, although appearing grossly of almost normal size, showed histologically, in all cases in which the organ could be recognized with certainty, initial or limited neoplastic changes. Lymphomatous tissue at the site

Fig. 1. C57BL mouse implanted with multiple syngeneic new-born thymuses and treated with urethane in drinking water. Large neoplastic mass at the graft site, 130 days after the end of urethane administration.

of implantation, as well as in the various organs involved by the generalized disease, was composed of cells of lymphoid type.

Present data suggest that grafts of neonatal thymus make susceptible to the leukaemogenic action of urethane the otherwise resistant mice. Since in our experiments lymphomas constantly arose from the implanted thymus(es), it is possible that the positive results obtained in both the experimental groups are correlated with the availability in the graft of cells particularly susceptible to urethane-induced damage leading to neoplasia. On the other hand, the finding of the highest susceptibility in the group implanted with multiple thymuses seems to indicate that a quantitative factor is involved in the process of neoplastic transformation of the graft. Thus it could be assumed that in a single thymus graft the number of cells sensitive to the weak leukaemogenic activity of urethane scarcely reaches the critical level necessary to initiate successfully a lymphomatous growth under the present experimental conditions. However, the mechanism through which a greater mass of thymic tissue influences leukaemogenesis, that is, by contribution of more target cells and/or production of larger amounts of humoral substance, remains to be elucidated.

The work was supported by grant DRG-808 from the Damon Runyon Memorial Fund for Cancer Research and by a grant from Consiglio Nazionale delle Ricerche, Roma. One of us (G. T.) is also holder of a fellowship from the Lady Tata Memorial Fund.

RADIOBIOLOGY

Bone Marrow Allografts in Thymectomized X-irradiated Dogs

ALLOGENEIC bone marrow transplantations in 1,000-r. irradiated dogs are therapeutically ineffective. Our earlier results¹ made it possible for us to suggest that transplanted haemopoietic cells became immunologically active against the recipient's lymphocyte antigens. All the dogs invariably indicated within 6-7 days of transplantation profound leucopenia followed by a sharp increase in white blood cell count at the cost of peculiar mononuclear hyperbasophilic cells resembling immune B precursors or transformed lymphocytes in phytohemagglutinin leucocyte cultures. On the next day only lymphocytes were observed in the blood; their count progressively decreased, and the animals died.

Taking into consideration previous results²⁻⁷ which showed that adult thymectomized mice failed to restore immunogenesis after radiation and bone marrow transplantation, and that immunological competence of radiation chimeras apparently are restored by transplanted bone marrow cells which act as lymphoprecursors in thymus^{8,9}, we supposed that transformation of transplanted haemopoietic cells into lymphocytes in dogs also requires a thymic factor.

To prove this assumption we performed experiments in thymectomized adult dogs. Thymectomy was performed under intravenous pentobarbital anaesthesia and artificial respiration through sternal cutting. One to two months after the operation the dogs were X-irradiated with 1,000-r. (2 days running with 500-r.). The day following the last radiation the dogs were injected intravenously with $7.4-9.2 \times 10^8$ viable nucleated bone marrow cells in 250-300 ml. Hanks's solution. Bone marrow cells were pressed out from the vertebrae and epiphysis femur and humerus. Simultaneously the dogs were transplanted with donor's skin (the pinch graft method¹⁰ was used). The dogs received daily intramuscular injection of 200,000 units of penicillin and 100 mg of streptomycin.

Thymectomy as such did not influence the haematological picture, in particular lymphopenia. The degree of radiation disease in these dogs was very heavy. Four dogs died 6-7 days after radiation before any re-population of the bone marrow graft appeared. At autopsy they showed large haemorrhages. Two dogs died 21 and 12 days after radiation. In one of these dogs (Fig. 1) there was sharp and quickly developing leucopenia, especially lymphopenia. However, 5-6 days after bone marrow transplantation the leucocyte count rapidly increased due to proliferation of donor cells. From the 7th day until death, donor leucocytes were identified in the blood of the dog (sex chromatin). As can be seen from Fig. 1, almost all leucocytes of this dog were polymorphonuclear. No hyperbasophilic cells appeared except during the 7th-8th days, when a small quantity of these cells was seen; scarcely any lymphocytes were present. White blood cells continued to increase—5,350 cells/mm³ on the 13th day and 13,150 cells/mm³ on the 21st day. In myelograms an insignificant quantity of hyperbasophilic cells was observed during the 7th-13th days after radiation. It should be noted that since the operation was performed on the sternum, bone marrow for investigation was taken from

the iliac crest which was badly re-populated in this experiment. In spite of a good leucopoietic restoration, anaemia progressed; the haemoglobin value had fallen by the 17th day from 15.2 g per cent to 8.6 g per cent and the red blood cell count from 5.4×10^6 to 3.0×10^6 cells/mm³. Death of the dog was caused by renal haemorrhage. At autopsy fatty bone marrow was found in the hind legs, while in the sternum, ribs and vertebrae bone marrow was active, rich in haemopoietic red and white cell lines. Lymphoid tissues of the spleen and lymphoid nodes were atrophied. The skin graft up to the death of the dog was in good condition, and was vascularized; there were no signs of any rejection.

Similar results were indicated by the second dog. Re-population of the bone marrow graft was active. Three days later, the bone marrow was injected and there appeared, in myelogram: stem cells, immature red and white cell lines which were practically absent before the bone marrow graft. Five days after transplantation the number of white blood cells increased; their amount rose from 100 cells/mm³ to 1,400 cells/mm³ in 2 days. Donor leucocytes (female in male) were identifiable up to the dog's death. The white blood cell count was fully conditioned by the increase of polymorphonuclear cells. Hyperbasophilic cells were absent in peripheral blood; lymphocyte content was not above 2 per cent. In bone marrow few hyperbasophilic cells were observed until just before death (12th day). At autopsy hypoplasia of haemopoietic and aplasia of lymphoid tissues were seen. The haemorrhagic syndrome was insignificant, and the cause of death was not established. The skin graft was in good condition.

Thus in neither dog did we observe any significant transformation of haemopoietic cells into lymphocytes. The decisive role of the thymus in such transformations is obvious from the fact that, without any exception, in all irradiated dogs (more than 40), similarly treated but without thymectomy, clear transformation of haemopoietic

Fig. 1. White blood cell count and myelograms in a thymectomized dog irradiated with 1,000 r. On the day after radiation the dog received allogeneic bone marrow. (1) Reticular cells; (2) stem cells; (3) immature myeloid cell lines; (4) mature myeloid cell lines; (5) erythrocytic cell lines; (6) lymphocytes; (7) plasmacytes; (8) hyperbasophilic cells. Above myelograms—bone marrow cell count in 1 mm³. ○, Leucocytes; △, neutrophils; □, lymphocytes; ■, hyperbasophilic cells.

cells into lymphocytes developed. These results suggest that for large animals, including man (just as for mice), the thymus is necessary for functional differentiation of polypotent stem cells into lymphoid precursor. These preliminary results indicate that even a strongly reduced thymus in adult dogs is effective. By analogy with the results already cited²⁻⁹ one is led to believe that the thymus of adult large animals and man plays a part in the restoration of immunogenesis after radiation, 'teaching' remaining stem cells. In connexion with this assumption it seems reasonable to attempt to delay the restoration of immunogenesis (depressed by massive whole-body irradiation and cytostatics) by preliminary thymectomy prior to transplantation of tissues and organs in man.

An Unusually Radioactive Fossil Fish from Thurso, Scotland

A PLATE of *Homosteus* from Clardon Haven about two miles east of Thurso was found to be radioactive to the extent of 1.2×10^4 γ /min/g. In order to characterize the radioactive isotopes present, the energies of the emitted γ -rays were measured using a γ -scintillation spectrometer.

The spectrometer was a 3 in. \times 3 in. sodium iodide phosphor used in conjunction with a photomultiplier, a high-gain amplifier and a 512-channel pulse-height analyser.

The energy range 80 keV–3,500 keV was examined and from the absorbed energies it was evident that the radioactivity was due to the decay chain of ^{238}U with

Fig. 1. Autoradiograph of a polished section of the bone of *Homosteus*. Scale, cm. The extremely bright spots are due to α -particles

some contribution from the ^{232}Th chain. The component of these chains and the appropriate gamma energies as shown in Table 1.

To assess the distribution of activity across the specimen a section was polished and an autoradiograph was obtained using industrial X-ray film (Fig. 1). The distribution is not uniform but is concentrated into a few small areas.

A quantitative examination using the spark excite emission spectrum examined by a Hilger medium spectrum graph indicated the chemical constituents as being major, calcium; minor, strontium, phosphorus, magnesium; heavy trace, barium.

The fact that the major activity was due to the decay chain of ^{238}U differs from previous results reported by Bowie and Atkin¹, who, working on an unidentified *Homosteus* plate (GSM 89090), found the major activity to be due to the decay chain of ^{232}Th .

Similar examinations were made on a small specimen of *Dipterus valenciennesi* from Scrabster Brae about 1.5 miles west of Thurso and on a specimen of *Thursius pholidotus* from the shore of Thurso Bay about one mile west of Thurso. These specimens, of similar age from stratigraphical evidence, showed no unusual activity. It would therefore seem that we only find excessive radioactivity in those fossil fishes having heavy dermal armour, for example, the arthrodira.

The penetrating γ -photons from the $4n+2$ series can be readily observed using a sensitive portable γ -detector which could be a useful aid in locating specimens in the field.

Continuous Irradiation of HeLa Cells at –196° C

THE incorporation of a suitable quantity of tritiated water in the growth medium permits the continuous irradiation of cells cultured *in vitro*. A uniform source of β -radiation is thus provided which can be used in a variety of cell culture techniques. Some observations on the effects of continuous irradiation of HeLa cells grown as a monolayer at 37° C have already been published^{1,2}. This communication reports some results of the continuous irradiation of HeLa cells at –196° C.

HeLa cells in logarithmic growth were suspended at 10^6 cells/ml. of Eagle's medium plus 20 per cent pooled man serum plus 10 per cent dimethyl sulphoxide and added into 1 ml. aliquots. Suitable amounts of tritiated water were incorporated in the medium of the aliquots to be continuously irradiated. The aliquots were sealed in glass ampoules and cooled by the technique of Nagington and Greaves³ down to -196°C in a liquid nitrogen refrigerator (by the courtesy of Dr. T. S. L. Beswick and Miss Ann Mostratos, Department of Virology, University of Manchester). In each experiment all the ampoules, control and treated, were maintained at this temperature for the same length of time, and the treated cells would be continuously irradiated at two different dose-rates to totals of 1,000 or 2,000 rads, respectively, in either 20 or 40 days.

At the end of each experiment the ampoules were removed from the liquid nitrogen and plunged directly into a water bath at 37°C . Each 1 ml. aliquot of cells was then diluted to 10 ml. in fresh growth medium (Eagle's medium plus 10 per cent pooled human serum) and the cell number was again determined to confirm that all the cells had survived at this stage of the experiment. Replicate single cell clonal cultures were then inoculated by the technique of Puck and Marcus⁴ using the same inoculum size for all cultures, irradiated and control. After incubation for 10 days at 37°C the colonies were scored; comparison with the controls gave the fraction of cells surviving each régime of continuous radiation at -196°C , determined from the average of six plates.

The surviving fractions are shown (Table 1) for each experiment and combined as an average percentage for each dosage régime. Although these average percentages are all lower than the controls, the only fractions which are significantly different are those after the 2,000 rads total dose given over 20 days at 100 rads/day. The variation between individual experiments is attributable to the lower plating efficiencies which follow the freezing technique. Nevertheless, one definite conclusion can be drawn from all these experiments: namely, that the large total doses of continuous irradiation had a very small effect on HeLa cells at -196°C .

In considering the interpretation of these results, the following facts are relevant. Continuous irradiation at 37°C leads to very little depression in the number of HeLa cells at dose-rates of 50 rads/day or less¹ since the radiation damage is spread over many cell cycles, and growth of the surviving cells may conceal the small proportion of cells sterilized per cell cycle. On the other hand, with acute doses (for example, 100 rads/min) the radiation is delivered during a small fraction of one cell cycle, and growth during that time is negligible. The proportion of surviving cells after an acute dose of 2,000 rads is reduced to about 10^{-6} (leaving a negligible number of colonies to be counted in a constant inoculum experiment).

One might expect that a dose of 2,000 rads delivered at 100 rads/day at -196°C would produce the same effect as an acute dose delivered at 100 rads/min at 37°C . Cellular metabolism will be reduced to a minimum at -196°C and one would expect the accumulated 2,000

rads to produce as much damage over at least as small a fraction of one cell cycle as an acute dose at 37°C .

It is known, however, that acute radiation is less effective at lower temperatures. Stapleton and Edington⁵ found the sensitivity of *E. coli* to be reduced at sub-freezing temperatures. Similar observations have been described by Webb *et al.*⁶ for dry bacterial spores, and the phenomenon has been discussed in subsequent papers by Powers and his colleagues⁷.

In mammalian cells (HeLa) Belli and Bonte⁸ found an increase of radio-resistance by a factor of 1.25 by decreasing the temperature from 37°C to 5°C . They point out quite correctly that the phenomenon is unlikely to be due to any degree of anoxia. At 5°C , however, diffusion of radicals is so little affected that it is difficult to think of a suitable radiation chemical explanation of their observation. Dawson *et al.*⁹ found a two-fold increase in radio-resistance of HeLa cells at -79°C when the mobility of free radicals would presumably be reduced.

At the temperature used in our experiments irradiation still produces ions, electrons, hydrogen atoms and free radicals in the solid matrix. The electrons will be captured by positive holes and/or imperfections in the solid matrix. The species capable of movement at a temperature of -196°C are presumably hydrogen atoms; the larger molecular fragments would be expected to be held in position. The hydrogen atoms may react with free radicals and may reduce some of the effects of radiation by reducing the number of radicals. Recombination of free radicals, especially fragments of macromolecules, may occur during the rise of temperature before thawing.

Hatching Time of Turtle Eggs

Jayakar and Spurway¹ have reported possible bimodality not only in egg-laying time by a turtle (*Testudo elegans* Schoepff) but also in hatching time. Evidence from other species of turtles may be helpful in interpreting their observations.

Several species of marine turtles, of tropical or sub-tropical regions, are known to lay more than once per season²⁻⁴, whereas terrestrial and fresh-water forms of temperate zones typically lay all the eggs of the year at one time⁵. Duration of incubation is dependent on environmental conditions, particularly temperature^{2,3,5,6}.

In my own experiments on turtle embryos over the past several years, I have found that hatching time for controls varies by only a few days for a given species even of different clutches, according to the temperature of incubation (Table 1). Within a given clutch of eggs there is an even smaller time-range. Hatchling size (carapace length) is positively correlated with egg size; in the very few instances in which the hatchlings were weighed the larger turtles were heavier than the smaller. There seems to be no pattern as to hatching sequence of large and small specimens.

Turtle hatchlings differ notably in their behaviour (cf. Carr⁷ for adults of *Terrapene carolina carolina* (Linné)). Some are markedly aggressive, whereas others appear

<i>Caretta caretta caretta</i>	30° C	2 (1)	54-55	54.5
<i>Chelydra serpentina serpentina</i>	28° C	9 (3)	55-62	58.0

* Incubation of eggs in any one group was begun at one time, in June or July. Room temperature varied considerably, but averaged close to 28° C. The dishes of eggs at constant temperature were kept in a water bath.

† The number in parentheses after number of hatchlings indicates the number of different clutches of eggs represented in each group.

timid and retiring. In my investigations the eggs are incubated in glass dishes between two layers of moistened absorbent cotton⁷. At the onset of hatching observations are recorded at least every 12 h. Some newly hatched specimens of *Chelydra serpentina serpentina* (Linné) have made their way out of the dishes, off the table, out of the laboratory, and one even down a flight of steps, all within a 12-h period. Others, on the contrary, have hidden themselves under the cotton or within the egg shell and have made no observed attempt to explore even after several days.

Miss Karen Diamond of Rockville, Maryland, told me of watching a Carolina box turtle, *Terrapene carolina carolina* (Linné), make a nest and lay her eggs under a rose bush in nearby Kensington on May 10, 1963. As the summer wore on, the spot was examined frequently for signs of emerging hatchlings. Finally, near the end of September, about 140 days later, the nest, between 4 and 6 in. deep, was dug up and revealed egg shell fragments and three live hatchlings with no sign of the yolk sac on the plastron. All three were 'timid' turtles⁸.

Domantay⁴ reports for *Chelonia mydas*, and Caldwell⁵ for *Caretta caretta caretta* (Linné), that the hatchlings usually emerge from the nest together, a fact which suggests that the more active ones open the way for the others.

In view of the foregoing evidence concerning other species of turtles, I suggest that the late emergers of *Testudo elegans* Schoepff as reported by Jayakar and Spurway¹ were not slow in developing but rather inactive as hatchlings, and that the correlation of low weight with late emergence from the hatching site is due to the yolk having been used up during the prolonged stay in the soil.

This work was supported in part by U.S. Public Health Service research grant AM 01766 from the National Institute of Arthritis and Metabolic Diseases.

Development of the Ovule in a Species of *Cissus*

In an investigation of the floral morphology and embryology of the Vitaceae the following features were observed in the development of the ovule of *Cissus trilobata* Lamk. collected from Changanacherry, Kerala State, India.

The ovule is anatropous, bitegmatic and crassinucellate. Of the two integuments, the inner which projects beyond the outer is initiated first by periclinal divisions in the protoderm simultaneous with the differentiation of the

Fig. 1. Longitudinal section of the ovule ($\times 130$). oi, Outer integument; ii, Inner integument.

ovular archesporium in the first hypodermal layer. develops faster than the nucellus and not only encloses the latter but also grows very long, 2-3 times the length of the nucellus, into a tubular structure which is thrown into folds and coils (Fig. 1). Although it is known that in other members of the Vitaceae the micropyle is formed by the inner integument¹⁻⁴, coiling and folding of the integument have not so far been mentioned. Moreover, such a long, coiled, and folded micropylar canal is not reported in any of the flowering plants.

Marsupial Spermatozoa Pairing in the Epididymis of American Forms

In 1962 Biggers and Creed¹ pointed out that conjugation (henceforth called pairing) of spermatozoa is a normal occurrence in the epididymides of the North American opossum (*Didelphis marsupialis virginiana* Kerr). Evidence has now been obtained which shows that this phenomenon is found in the majority of, if not all, marsupials in the American continents, and that, if it occurs in Australasian marsupials, it is likely to be exceptional. Also, three morphologically distinct types of spermatozoa have been found to exist in the extant American group, which consists of 69 species² grouped into 15 genera and two families. Our observations are summarized in this report.

The species of marsupial we have examined are shown in Tables 1 and 2. In most cases, fixed specimens of the testes and epididymides were examined histologically. However, the living epididymal spermatozoa of *Philander opossum* (four-eyed opossum), *Marmosa mexicana* (murine opossum), and *Caluromys derbianus* (woolly opossum) have also been examined.

Pairing of spermatozoa has been observed in the epididymides of all the species of American marsupials shown in Table 1. In no instance was pairing observed in sections of the testes. The only genera we have not been able to examine are *Glironia*, *Dromiciops*, *Caluromys*, *Lutreolina* and *Notodelphis*. A sufficient number of data are available on the two sub-species of *Didelphis* and *Philander* opossum to indicate the incidence of pairing within species. Out of 92 specimens of *D. m. tabascensis*, 88 (95.7 per cent) were paired, and out of 56 specimens of *P. opossum*, 54 (96.5 per cent) were paired. This incidence is very similar to that found for *D. m. virginiana*¹. Thus the pairing of

spermatozoa in the epididymides is a widespread, if not universal, phenomenon in the American stock of marsupials. It is impossible at present to determine the extent of pairing in the epididymis and the degree of variation between individuals. This will only be possible when methods of collecting ejaculates from these species have been devised.

The pairing of spermatozoa in the epididymides has not been observed in any of the species of Australasian marsupial shown in Table 2, and in no case was pairing observed in sections of the testes. Thus it seems unlikely that pairing of spermatozoa occurs in the epididymides of the Australasian stock of marsupials.

During the course of this work three distinct morphological types of spermatozoa have been found in the American marsupials. These will be designated the *Didelphis*, *Caluromys* and *Caenolestes* types respectively, and pairs of them are illustrated in Figs. 1, 2, 3. *Didelphis* is the well-known type, and this has been described elsewhere^{1,3}. *Monodelphis*, *Philander*, *Metachirus*, *Chironectes* and *Marmosa* all have this morphological form of spermatozoa. The spermatozoa of *Caluromys* possess saucer-shaped heads with the mid-piece inserted into the convex side, and the acrosome lying in the concave side. Pairing occurs by apposition of the two concave sides. The spermatozoa of *Caenolestes* have only been observed in fixed material. Unfortunately, this is a very rare species indigenous to localized areas of the Andes, and it is very unlikely that living material will be obtained. The spermatozoa are very rectilinear in shape with a niche on one side from which the mid-piece arises. Pairing occurs by apposition of the edges opposite the insertion of the mid-piece.

The phenomenon we have described as pairing was first observed in *D. marsupialis* by Selenka⁴, who referred

to it as 'copulating' spermatozoa. This name was used by Von Korph⁵, who made the crucial observation that the spermatozoa arise as single cells in the seminiferous tubules, and that the pairing only occurs after the gametes reach the epididymides. Later, Wilson⁶ objected to this label, and introduced the word 'conjugating'. However, this word has acquired a specific meaning in biology with reference to the union of gametes in unicellular organisms. For this reason, we prefer the simple descriptive word 'pairing' to describe the phenomenon. Perhaps, when experimental work has elucidated the phenomena involved in this highly oriented adhesion of cells, a more explicit word may be coined for its description.

The finding of three morphologically distinct types of spermatozoa in the few genera of American marsupials is pertinent from a taxonomic point of view. Osteological and palaeontological evidence was interpreted by Reig⁷ to suggest that *Caluromys*, *Dromiciops* and *Glironia* are related members of the sub-family Microbiotheriinae formerly thought to be extinct. The finding that the spermatozoa of *Caluromys* are morphologically different from that of the sub-family Didelphinae may therefore be systematically significant. An examination of the sperma-

tozoa of *Dromiciops* and *Glironia* to see if they are morphologically similar to those of *Caluromys* would elucidate this problem, but unfortunately this has been impossible because of the rarity of these species. The observation that *Caenolestes* has spermatozoa morphologically distinct from other American marsupials is of interest because of the unusual features of this survivor of an ancient marsupial group of the Tertiary epoch⁸. These animals are unique in that they possess affinities with members of the super-family Phalangerioidea found only in Australasia, thus providing a possible connexion between the American and Australasian groups of marsupials⁹. Investigations of the morphology of marsupial spermatozoa, however, indicate no similarity between the American and Australasian forms¹⁰, and therefore, so far as this character is concerned, there is no affinity between the two major marsupial groups.

The fact that pairing of spermatozoa has been observed in all types of American marsupial which have been examined, transcending two natural families and three morphological types, and has not been observed in Australasian marsupials, indicates that both the *Caenolestidae* and *Didelphidae* are derived from a common ancestral stock, the descendants of which evolved only in the Americas. Furthermore, pairing of spermatozoa, whatever its function, must have become established early in the evolutionary history of the group.

Record of the Bivalve Gastropod *Berthelinia limax* (Kawaguti and Baba 1959) from the Indian Ocean

A LIVING bivalve gastropod of the order Sacoglossa, found in Japan by Kawaguti and Baba¹ in 1959, was described as a new genus and species *Tamanovalva limax*. Keen and Smith², Baba³ and Taylor and Soh⁴ synonymized the genus *Tamanovalva* Kawaguti and Baba 1959, with the Eocene Paris Basin fossil genus *Berthelinia* Crosse

Fig. 1. Two live specimens of *Berthelinia limax* (Kawaguti and Baba 1959) ($\times 25$)

1875 and included it under the sub-family Berthelininae Beets, 1949, of the family Jullidae Dall, 1898. Since the living members of this genus have been reported from number of other Pacific localities in Japan⁵, Australia⁶ and Hawaii⁷, and from Jamaica⁸ in the Atlantic. The purpose of this communication is to record the collection of living specimens of *Berthelinia* for the first time from the Indian Ocean region.

Recently, while examining nudibranch molluscs near the jetty of the Central Marine Fisheries Research Institute at Mandapam Camp facing the Gulf of Mannar, came across four specimens of small bivalve gastropod found attached to the roots of the green alga *Caulerpa racemosa* (Forsskal) J. Agardh, which on close examination resembled *Berthelinia limax* in all essential features (Fig. 1). The measurements of the four specimens are given in Table 1.

Table 1		
Specimen No.	Length (mm)	Height (mm)
1	2.76	1.94
2	2.53	1.76
3	2.41	1.70
4	2.00	1.35

The habitat of *Berthelinia* appears to be restricted to various species of *Caulerpa* on which it feeds. Its known distribution along with the algal habitat is shown in Table 2.

The present specimens resemble the Pacific species and the differences noted are very minor and not sufficient to warrant any specific separation. They are, however, distinct from the West Atlantic species, *Berthelinia caribbea* Edmunds¹⁰, where the shell valves are green or grey-green often tinged brownish, with more or less distinct yellow rays.

The animals are leaf green in colour with auriculate rhinophores ornamented with opaque white spots. The head, neck and sole are light green in colour, while the

Table 2

Spec. No.	Species	Algal habitat	Reference	Locality

2	<i>Berthelinia typica</i>	<i>Caulerpa scalpelliformis</i>	Burn (ref. 6)	Torquay, Victoria, Australia
3	<i>Berthelinia australis</i>	<i>Caulerpa scalpelliformis</i>	Burn (ref. 6)	Torquay, Victoria, Australia
		<i>Caulerpa brownii</i>		
4	<i>Berthelinia chloris</i>	<i>Caulerpa simpliciuscula</i>	Keen and Smith (ref. 2)	Puerto Ballandra Bay, Baja, California
		<i>Caulerpa racemosa</i>		
5	<i>Berthelinia</i> sp?	<i>Caulerpa sertularioides</i>	Kay (ref. 8)	Koloa, Kauai, Hawaii
6	<i>Berthelinia caribbea</i>	<i>Caulerpa racemosa</i>	Edmunds (ref. 10)	Port Royal, Jamaica
7	<i>Berthelinia limax</i>	<i>Caulerpa verticillata</i>	Present work	Mandapam Camp (Gulf of Mannar, India)
		<i>Caulerpa racemosa</i>		

tle and the liver are deep green. A few irregularly red dark green spots are present on the liver. The valves of the shell are equal in size, light green in colour, extremely thin and fragile, with a smooth surface which is marked by fine growth lines. The helicoid protoconch is translucent and of one and half whorls, attached to the posterior extremity of the left valve as in *Berthelinia ax.* The protoconch is directed backwards extending horizontally over the right valve. The position of the yellowish white circular attachment of the adductor muscle is as in *B. limax*.

One of the specimens laid an egg string which was kept under observation. The early development agreed in all essential respects with the observations of Kawaguti and Baba¹ and Kawaguti and Yamasu^{11,12} on *B. limax*.

With the record of the genus *Berthelinia* from the Indian coast it could be presumed that the species of the genus are distributed throughout the coastal waters of the warmer seas. A careful search might prove that it is widely distributed in the Indo-Pacific waters.

I thank Dr. Umamaheswara Rao for identifying the species, Dr. P. S. B. R. James for advice, and Mr. K. G. Ambiar for the photograph.

Spore Discharge in *Lepiota konradii*

RECENT investigations¹ based on laboratory experiments have shown that ballistospore discharge is much affected by the humidity and temperature of the ambient air. The observations reported here are based on field studies during which an effort was made to determine the effect of temperature and humidity on ballistospore discharge under natural conditions.

On the morning of January 15, 1965, three fruiting-bodies of *Lepiota konradii* Huijsman ex P.D. Orton² were found growing in the Biological Garden, University of Ife, Ibadan, Nigeria; by noon, their pilei were beginning to expand.

An electric-driven Hirst spore trap was set up near these fruiting-bodies. The trap was placed so that the orifice was at a height of 27 cm above ground-level. The horizontal distance of the orifice from the pileus of the nearest fruiting-body was 56 cm.

Sampling at the rate of 0.6 m³/h was continued until the fruiting-bodies were found to be withering, drying, and tottering as if they were about to fall. The sampling period was January 15–18, 1965.

The ballistospores being sticky themselves, clean slides were used without any adhesive. These were changed daily at 1300 h Nigerian Standard Time. After exposure, slides were mounted for examination in glycerol and scanned under low magnification. Counts were made on cross traverses 34 μ wide and 4 mm apart, representing 2-h intervals. The numbers of spores counted were then converted into an estimated number per cubic metre of air.

Records of temperature and humidity were obtained by means of a Casella thermo-hygrograph situated under the roof of the spore trap.

Fig. 1. Hourly mean concentration of ballistospores

The results shown in Fig. 1 clearly indicate a correlation between spore discharge and relative humidity. The increased rate of spore discharge at 1800 h and reaching a maximum (6,200 spores/m³ air) at 0400 h—a period of rapid liberation of ballistospores—corresponds quite closely with that of decreasing temperature and increasing relative humidity of the surrounding atmosphere.

Counts at 2200 h and 0200 h show, however, that the concentration of spores in the 2-h periods preceding these times had been slightly reduced. This needs further investigation, which is being planned. It was probably due to a change in the direction or the velocity of the wind, or possibly to the fact that nearly all mature spores were liberated during the early part of the period of high humidity, so that there were not many spores left for liberation during the later part. On the other hand, the maximum discharge recorded at 0400 h might have been due to a recovery in the number of mature spores.

Shortly after 0400 h the rate of spore discharge decreased gradually and reached a minimum (1,000 spores/m³ air) at 0800 h. The relative humidity then recorded was fairly low (68 per cent).

Again there was a further large increase (to 7,700/m³) in concentration of these ballistospores in the air at 1000 h. Such abundant liberation was correlated with a sudden increase in humidity caused by a slight trace of rain. Thereafter the spore liberation decreased very rapidly, so that by 1200 h the spore concentration in the atmosphere was only 300/m³ and by 1400 h liberation had apparently fallen to zero. For, although subsequent observations indicated numerous dust and smoke particles in the air, no *Lepiota* ballistospores were found impacted on the slides.

These observations also show that the spore discharge period for the fruiting-bodies investigated began at 1400 h in the afternoon and ended about 1200 h the next morning, being accordingly of about 22 h duration.

The observations reported here indicate that temperature and humidity control ballistospore discharge in the field—as in the laboratory. It would be interesting to know to what extent, if any, temperature and humidity control the development of the ballistospores.

FORESTRY

Induction of Tension Wood with the Anti-auxin 2,3,5-Tri-iodobenzoic acid

THE xylem formed on the upper side of arborescent angiosperms in reaction to inclination is often of the abnormal tension wood type. A complete discussion of tension wood anatomy is given in a recent review by Wardrop¹. In brief, it is characterized by the presence of a large number of thick-walled, 'gelatinous' fibres of unusually low lignin content, and a reduction in the size and number of vessels over that of normal wood.

The reaction wood observed in leaning coniferous stems occurs on the under side. Since reaction wood in conifers can be induced to form on application of indolyl-3-acetic acid (IAA) to erect stems²⁻⁴, the mechanism of its formation in leaning trees is generally thought to be associated with supra-optimal concentrations of IAA or closely allied growth-promoting substances. However, application of IAA to the upper surface of young, bent seedlings of *Populus monilifera* prevented the formation of tension wood⁴. In this latter study, untreated inclined branches of *Populus alba* were observed to form tension wood on their upper sides in association with low levels of IAA and the presence of growth inhibitors. As a logical extension of this study, we investigated the possibility of inducing the formation of tension wood in an erect stem of a hardwood by applying a synthetic anti-auxin. The use of such anti-metabolites in physiological investigations of tension wood formation has also been suggested by Berlyn⁵.

The anti-auxin 2,3,5-tri-iodobenzoic acid (TIBA) was selected for use. It is known to act as an IAA antagonist either through direct competition with auxin or by blocking its movement about the plant⁶. Larson⁷ has employed this substance with *Pinus resinosa* to induce the formation of tracheids of reduced radial diameter, a response contrary to that evoked by application of IAA. A lateral exogenous application of TIBA in lanolin paste (1:100) was applied to a four-month-old white elm (*Ulmus americana* L.) seedling 5 mm in diameter. After first scraping the outer bark at a point 7 cm above the level of the rooting medium ('Perlite' irrigated with a complete nutrient solution), application was made in a band 5 mm wide completely around the periphery of the stem. At the conclusion of a 35-day period the stem was collected by cutting into 3-cm lengths. These pieces were aspirated in FAA solution and sectioned transversely at three different levels: (1) directly above the point of application of TIBA, (2) 2 cm below, and (3) 5 cm above this point. Sections were stained in safranin and fast green before microscopic examination.

The wood formed by the cambium as a result of application differed markedly from that produced before treatment (Fig. 1). Directly above the point of application, the mature wood formed in response to TIBA consisted of four bands of rectangular conductive cells resembling coniferous tracheids due to their orientation into tangential and radial rows (Fig. 2). These bands of conductive tissue alternated with three bands of fibres, the last of which was almost entirely gelatinous. At the widest point, the number of mature cells in a radial row through these bands totalled about 60, indicating a very rapid rate of cell production. The areas sampled above and below this location had approximately the same features, namely: a zone of response to TIBA only half the radial width of position (1); conductive tissue similar to that described above, except in shorter tangential lines; fibrous zones which were exclusively gelatinous (Fig. 3).

Equal parts of hydrogen peroxide and acetic acid were used to macerate the layer of wood formed in response to TIBA application. Examination of the pulp verified that the conducting elements seen in transverse section were vessel segments, approximately 0.13 mm long, with simple perforations and heavy spiral thickenings. The vessel ele-

ments of the normal wood were likewise simply perforated but were often twice the length of the former, and only weak spiral markings confined to the latewood.

The faster growth rate, reduction in size of vessel elements, and the formation of gelatinous fibres, especially in the two locations more remote from the point of application of TIBA, establish a cambial response leading to tension wood formation. The fact that the total volume of vessels was not reduced must be regarded as an anomaly. Nevertheless, these results lend support to the hypothesis that tension wood forms in response to an auxin deficiency. In naturally leaning hardwood stems and inclined branch the auxin deficiency probably results from the influence of gravity on its distribution, leading to the conclusion

Fig. 1. Appearance of xylem formed in *Ulmus americana* stem before application of TIBA

Fig. 2. Appearance of xylem formed in erect *Ulmus americana* stem immediately above the point of application of TIBA. Gelatinous fibres were present only in the third band (top of photograph)

Fig. 3. Comparison of xylem fibres formed in erect *Ulmus americana* stem, 5 cm above the point of application of TIBA. The central tangential band of small vessels and axial parenchyma separates fibres formed before (lower half) and after (upper half of photograph) application of TIBA.

Wardrop¹ that gravity is a major factor governing the formation and distribution of tension wood.

This study is continuing with extensive sampling of 14 angiospermous species on which TIBA has been applied to lateral and excised apical surfaces.

Leucoanthocyanins of White Pine in relation to Weevil Attack

LEUCOANTHOCYANINS may serve as growth-promoting substances¹ as well as precursors to tannin formation². Both these functions suggest that leucoanthocyanins may be involved in the complex of factors which influence pest resistance in plants. With this possibility in mind, an investigation of the leucoanthocyanins of eastern white pine (*Pinus strobus* L.) was carried out to determine the relationship between leucoanthocyanin content and susceptibility to white pine weevil (*Pissodes strobi* (Peck)).

In the only previous report dealing with leucoanthocyanins in *P. strobus*³, both leucocyanidin and leucodelphinidin were found in needles and bark, while the wood contained only leucocyanidin. No quantitative data were given in that report.

Parent trees of the control-pollinated progenies used in this investigation were located at the Morris Arboretum of the University of Pennsylvania, Philadelphia. Twelve trees of each progeny were examined in a 1952 test planting established by the U.S. Forest Service in Williamstown, Massachusetts. Significant variation in susceptibility to weevil attack has been reported for these and other pedigreed progenies⁴.

Leaders or leading lateral shoots of the current season were collected during the winter of 1963 and allowed to dry in the laboratory for one month. This procedure eliminated the problems encountered when working with resinous material. The bark (chiefly cortex) was scraped from the wood cylinder and the woody portion of the stem was further separated into wood and pith. All material was ground in a Wiley mill to pass a 20-mesh sieve.

Conversion of leucoanthocyanin to the coloured aglycone was accomplished by hydrolysing small samples of tissue (100 mg bark and wood, 15 mg pith) in 10 ml. of an *n*-butanol-3 N hydrochloric acid (5 : 1 v/v) solution in a sealed test-tube. This mixture was heated at 100° C in a water bath for 40 min. The transformation of leucoanthocyanins to aglycones may not be quantitative but alcoholic solvents are more than twice as efficient as aqueous solvents^{5,6}.

After cooling, the coloured extracts were spotted on Whatman No. 1 paper and chromatographed by the ascending method using Forestal solvent (glacial acetic acid-conc. hydrochloric acid-water, 30 : 3 : 10 v/v/v). Pure cyanidin and delphinidin were used as checks. Cyanidin was the only aglycone that could be identified from both parent and progeny trees. Larger samples of bark (up to 3 g) gave similar results.

In order to check further on the earlier report of the occurrence of both cyanidin- and delphinidin-yielding leucoanthocyanins in *P. strobus* bark, four native trees growing within a small area in New Hampshire were sampled. Of these trees, one yielded delphinidin and cyanidin in approximately equal amounts, while another gave no delphinidin. The two other trees were intermediate. Thus it appears that a detectable content of leucodelphinidin is not invariably present in *P. strobus* bark.

Quantitative determinations of cyanidin content in appropriately diluted extracts were made with a Bausch and Lomb 'Spectronic 20' spectrophotometer. This instrument had been calibrated at a wave-length of 550 mμ with known concentrations of cyanidin prepared from pure leucocyanidin (kindly provided by Dr. K. Weinges, Heidelberg) by hydrolysis in butanol-hydrochloric acid. Results, calculated as percentages of dry weight of tissue, are given in Table 1.

There were no significant or meaningful differences in the cyanidin content of bark or wood between trees that had been weeviled or 'unweeviled' in the past. Although there was significant variation among parents in wood cyanidin, the progeny averages were less than might be expected.

Progeny differences in pith cyanidin were highly significant, but again progeny averages were lower than expected and the difference between weeviled and 'unweeviled' trees was not significant. Cyanidin content of the pith was found to decrease with the time since origin. In the single tree tested, pith of the current season had 2.21 per cent cyanidin, while two-year-old and five-year-old pith contained 1.19 per cent and 0.19 per cent cyanidin, respectively.

Several one-year-old stems showed evidence of localized injury by natural causes. When cross-sections of these stems were stained in methanol-hydrochloric acid, it appeared that leucocyanidin had been translocated from the pith through the rays and had accumulated in the wood at the site of the injury. This movement of leucoanthocyanins in response to injury should be investigated further.

Table 1. CYANIDIN CONTENT OF VARIOUS TISSUES OF WHITE PINE LEADERS

Parent or progeny	Bark (per cent)	Wood (per cent)	Pith (per cent)
G-730	2.54	0.26	3.33
730 x 740	2.53	0.096	1.90
Weeviled	2.54	0.097	1.91
Not weeviled	2.73	0.094	1.86

MICROBIOLOGY

Apparent Suppression of Mutation Rates in Bacteria by Spermine

ONE of the chief obstacles to chemotherapy with antibiotics has been the frequent emergence of drug-tolerant bacteria. The availability of means to prevent or suppress the development of resistant cultures could have immense medical import as well as providing a valuable tool for the study of mutagenesis. Sevag and collaborators¹⁻³ reported that when polyamines were included in the culture medium of various micro-organisms, the outgrowth of drug-resistant populations in the presence of low concentrations of antibiotics was significantly delayed. They interpreted these observations as suggesting an antimutagenic role for the polyamines and further proposed that the site for this antimutagenic action is the DNA of the sensitive cells. Because of the theoretical implications of these observations it was of interest to establish in a more rigorous manner whether polyamines are antimutagens or whether the effects described by Sevag and co-workers could be explained in some other manner. This communication presents evidence that the inclusion of spermine in bacterial culture media resulted in a significant decrease in the random mutation rate of *Escherichia coli* and *Staphylococcus aureus*. The mutational events which were investigated were the one-step development of resistance to streptomycin and the back mutation to autotrophic growth by a tryptophan-requiring mutant. Spermine caused even more striking antimutagenic effects when mutations were induced by the inclusion of caffeine in the culture medium⁴ or by ultra-violet light. Future papers will seek to demonstrate that bacterial DNA could be the site of action of this compound⁵. A preliminary report on some of these experiments has already been given⁶.

E. coli (UC 879) and a tryptophan-requiring mutant (UC 707) were cultured in a minimal salts glucose medium⁷ supplemented with 20 µg/ml. L-tryptophan where required. *S. aureus* (UC 76) was cultured on a synthetic medium containing amino-acids, vitamins and salts⁸. To estimate the mutation rates a random fluctuation test, similar to the one described by Luria⁹, was used. This test assumes

that mutation rates are independent of absolute time and are dependent on the number of bacteria present and the generation time of the cultures⁹. The recent work of Kubitschek and Bendigkeit¹⁰ suggests that this assumption is likely to be warranted in this case. For each treatment 50 replicate 2-ml. cultures were inoculated with 100 cells each and at the end of 18 h of growth at 37°C the cultures were plated with nutrient agar containing 8 µg/ml. streptomycin sulphate. When 'back mutation' from tryptophan-requirement was studied, the cultures were twice washed in saline to remove residual tryptophan and plated in glucose salts agar. The number of plates in which no growth occurred was scored and the total number of cells per culture plate was established by plating appropriate dilutions on nutrient agar and counting the number of colonies present. The mutation rate was then calculated from the formula:

$$m = -(2.303 \log_{10} P_0)/N$$

where N is the total number of bacteria in a culture and P_0 the proportion of the total cultures which showed growth.

Table 1 is a summary of a number of experiments in which the random mutation rates to streptomycin resistance by *E. coli* and *S. aureus* were estimated, as well as two experiments in which the 'back mutation' from tryptophan requirement was studied. In all cases the mutation rates of cells which were grown in the presence of 150 µg/ml. spermine·HCl were clearly lower than those of controls. In most experiments the difference was statistically significant ($P = 0.01-0.007$ as determined from a χ^2 distribution). When spermine was added to control cultures at the time of plating, the mutation rate was the same as that of the controls (line 3, Table 1). Similarly, there was no change in the antimutagenic effect of spermine when the compound was removed along with the tryptophan in the washing procedure and not replaced when the cultures were reconstituted for plating (lines 6 and 7, Table 1). Thus to exert its antimutagenic effect, spermine must be present during the growth of the cells and need not be present during the plating. A reduction of the spermine concentration from 150 µg/ml. to 30 µg/ml. resulted in loss of the antimutagenic effect. However, replacement of the glucose salt medium with nutrient broth in no way influenced the antimutagenic action of spermine (lines 4 and 5, Table 1). Finally, in agreement with the observations of Sevag and Drabble¹, the colonies which grew in the presence of streptomycin were shown on sub-culture to be streptomycin-resistant and those which grew in the absence of tryptophan were shown to have lost their requirement for this amino-acid. Thus, growth in the fluctuation test truly reflected mutational events.

While the suppression of random mutation rate by spermine was real, there was a much more pronounced effect on mutations which were induced by the incorporation of 150 µg/ml. caffeine into the culture medium⁴ or by irradiation of the cultures with ultra-violet light. Table presents the results of these experiments. Each exper-

Table 1. ANTIMUTAGENIC ACTION OF SPERMINE IN RANDOM FLUCTUATION TESTS

Organism	Mutational end-point	Treatment	$N \times 10^6$	$M \times 10^{-10}$	$\frac{m \text{ control}}{m \text{ treated}}$	P
<i>E. coli</i> UC 879	Streptomycin resistance	Control	4.3	1.28	3.7	0.007*
		+ Spermine	4.0	0.35		
<i>E. coli</i> UC 879	Streptomycin resistance	Control; spermine added at plating time	4.3	1.18	1.1	> 0.25†
<i>E. coli</i> UC 879	Streptomycin resistance	Control—broth grown	5.4	1.07	1.95	0.002
		Spermine—broth grown	3.5	0.55		
<i>E. coli</i> UC 707	Trypt—Trypt†	Control	0.76	6.4	2.9	0.026‡
		Spermine	0.83	2.2		
<i>S. aureus</i> UC 76	Streptomycin resistance	Control	6.0	1.09	2.5	0.012‡
		Spermine	5.7	0.43		

The mutation rate, m , was computed from the equation $m = -(2.303 \log_{10} P_0)/N$, where N is the total number of bacteria per culture and P_0 the proportion of cultures which were free of mutants. Fifty replicate cultures were used for each treatment. P values are based on χ^2 distribution.

* This experiment is one of 7 similar ones which were performed and is the ranked median of these with respect to magnitude of P . The range in P values was 0.017–0.002 and the overall probability of null hypotheses was ≤ 0.001 .

† Versus control value, line 1.

‡ One of duplicate experiments with identical results.

Table 2. ANTIMUTAGENIC ACTION OF SPERMINE ON MUTATIONS TO STREPTOMYCIN-RESISTANCE INDUCED IN *E. coli* UC 879 BY CAFFEINE AND ULTRA-VIOLET LIGHT

Treatment	(See Table 1 for details)			$\frac{m}{m}$ control treated	P
	Initial $\times 10^{10}$	Surviving $\times 10^8$	$m \times 10^{-10}$		
Caffeine	0.8	—	1.5	11.5	≤ 0.001
Caffeine + spermine	1.7	—	0.13		
Control	1.5	—	0.48		
Ultra-violet, 25 sec	1.4	0.53	220	8.5	0.024
Caffeine + ultra-violet	3.2	0.66	26		
Control	1.4	—	0.46		

ent was repeated once with essentially identical results. The ultra-violet irradiation was accomplished with a testinghouse 36GT5 germicidal lamp at a dose of approximately 150 ergs/mm² to effect a killing rate of approximately 99 per cent¹¹. Individual aliquots of a culture which had been grown for 9 h on a shaker (with or without added spermine during growth) were irradiated in a darkened room. All further handling was carried out in the dark to prevent photoreactivation. In all cases cells grown in the presence of spermine had lower mutation rates than the control cells ($P = 0.02$).

The mutational event in all these experiments occurred in the absence of the indicator by which the event was scored. Furthermore, there was no effect on the growth rate of streptomycin-sensitive or -resistant organisms when spermine was included in the culture medium. Thus there is no chance that any form of selection could account for the observed changes in the incidence of mutations¹². Preliminary results suggest that other polyamines may also suppress the random mutation rate much as they were reported by Sevag and co-workers¹⁻³ to delay the outgrowth of resistant populations in the presence of antibiotics. It is concluded from these results that the antimutagenic action of polyamines is a general property of these compounds, that it is independent of the mutational end-point being measured, and that it is even more pronounced when mutations are induced than when randomly occurring mutations are studied.

We thank Mr. Jack I. Northan for assistance with the statistical analysis of the results.

VIROLOGY

Derivatives of 2-Aminoethyl-guanidine and of a Eugenol as Virus Inhibitors

It is a well-known fact that certain structurally different chemicals inhibit the synthesis of viral RNA¹⁻³. In this communication a few substances which inhibit virus multiplication are described. These are the following: 2-(β -aminoethyl) pyridine (AEP), its substituted derivatives; the 2-pyridyl-ethyl-guanidine sulphate (Pyg)⁴, the 2-(5-allyl-3-methoxy-2-hydroxy-benzyl)- β -(α -pyridyl) ethyl amine (H-99)⁵ and 'Ismelin' 2-octahydro-1-azocynil ethyl guanidine sulphate⁶. Guanidine hydrochloride was used as control.

Experiments were carried out on primary monkey kidney cell monolayer cultured in Petri dishes by the plaque method⁹. The virus inhibitory effect of chemicals was tested against 10-100 plaque-forming units of Sabin's type 1 (*LSc 2ab*) virus strain. The plaque assay has already been published in detail⁷. Usually 1 h after virus infection, plates were overlaid with nutrient agar containing 20, 50 or 100 μ g/ml. of substances respectively. Sometimes substances were added to the cell sheets, applying a second overlay 4, 24, 32 h after virus infection respectively. The results are presented in Table 1.

Table 1. EFFECT OF CHEMICALS ON THE PLAQUE-FORMING CAPACITY OF TYPE 1 (*LSc 2ab*) VIRUS STRAIN (SABIN)

Exp. No.	Treatment after virus infection (h)	Concentration of substances (μ g/ml.)	Controlled untreated plates	Denomination of substances				
				'Ismelin' Average	Pyg	H-99	AEP	Guanidine
1	1	100	130	Zero	Zero	Zero	N.D.	N.D.
	1	100	98	Zero	Zero	Zero	70	N.D.
	24	100	39	Zero	Zero	N.D.	N.D.	N.D.
3	1	100	137	Zero	Zero	Zero	N.D.	N.D.
	1	20	50	4	Zero	N.D.	N.D.	N.D.
	24	100	100	(Very small) N.D.	17	Zero	N.D.	Zero
4	1	100	49	Zero	N.D.	N.D.	N.D.	N.D.
	1	50	Zero	Zero	N.D.	40	N.D.	3
	1	20	Zero	Zero	Zero	Zero	N.D.	N.D.

*N.D., not done.

As Table 1 indicates, the Pyg was the most effective but its component the AEP had only a slight inhibitory effect. Substance H-99 showed a strong inhibition in a concentration of 100 μ g/ml., but at 20 μ g/ml. its effect was negligible. The inhibitory effect of 'Ismelin' was expressed at any given concentration (100, 50, 20 μ g/ml.). When 'Ismelin' was applied 4 h after infection it could inhibit the formation of visible plaques completely, and applying 24 h after infection the plaque number was strongly but not completely inhibited. In the case of Pyg, 4 and 24 h after virus infection the inhibitory effect was complete; moreover, 32 h after infection it was still at about 80 per cent. Consequently these support the hypothesis that 'Ismelin' and Pyg can inhibit the late phase of virus synthesis.

It is remarkable that the highly active chemicals are known as anti-hypertensive substances⁸, and one of them, 'Ismelin', is already being used as a therapeutic drug.

GENETICS

Puffing of Salivary Gland Chromosomes after Treatment with Carbon Dioxide

AFTER larvae of the Oregon R strain of *Drosophila melanogaster* had been placed in an atmosphere of CO₂ for 1 h late in the third instar, the salivary-gland chromosomes were examined and compared with those of a similar group of the same age. The chromosomal regions

Fig. 1

studied were eight regions known to puff: 85-86, 93, and 95 on the right arm of the third chromosome; 66, 71-72, 74-75, and 78 on the left arm of the same chromosome; and 2B on the X chromosome. The size of the puffs in the 84 glands examined were arbitrarily divided into four classes from smallest to largest and the data tabulated accordingly (Table 1). Although not all puffs were larger in the groups treated, the mean size of puffs III R 85-86, 93, and 95, and III L 66 was larger after exposure to CO_2 . The remainder showed no tendency to enlarge after such treatment. Larvae late in the third instar not used for chromosomal studies survived and developed into adults following the exposure to CO_2 . Many younger larvae died. These observations are reported because of current interest in the puffing pattern as presumed indication of localized production of RNA in response to hormonal stimulation. Recently we have found that ecdysone will produce puffing at this stage of larval development in some regions but not in others. Two not affected by CO_2 (I 2B and III L 74-75) showed an increase in mean size with ecdysone, and one (III L 71-72) failed to respond to either treatment.

Table 1. EFFECT OF CO_2 ON SIZE OF PUFFS EXAMINED IN CHROMOSOMES I AND III

Evidence for a Second 'Structural' Locus determining Human Phosphoglucumutase

At least seven isoenzyme components¹ of human phosphoglucumutase (PGM) can be distinguished electrophoretically (a-g, Fig. 1). Individual differences occur in the pattern of components present, and three common occurring phenotypes have been recognized (PGM 1, PGM 2-1 and PGM 2). They differ in the distribution of components a, b, c and d. Components a and c are present in PGM 1 and PGM 2-1, while components b and d are present in PGM 2-1 and PGM 2. The genetic evidence indicates that these phenotypic differences are due to pair of autosomal alleles (PGM^1 and PGM^2). Evidently a structural locus is involved, and it seems likely that one of these alleles determines the formation of a polypeptide common to a and c, while the other allele determines the formation of an alternative polypeptide common to b and d. The three phenotypes do not differ from one another in the occurrence of components e, f and g. This suggests that at least one other 'structural' locus is involved in the determination of these latter components.

Evidence for the existence of such a locus has now been obtained from the investigation of a family in which two unusual PGM phenotypes were found to be segregating. These new phenotypes are illustrated diagrammatically in Fig. 1. They will be referred to for the present as PGM (Atkinson) and PGM 2-1 (Atkinson), after the name of the family in which they occurred. The peculiar feature of the 'Atkinson' phenotypes involve the rapidly migrating (efg) set of components. Usually components e and f are very much more intense than component g. In the 'Atkinson' phenotypes components e and f, though present

Fig. 1. Diagram of starch gel showing PGM components observed in haemolysates from individuals of the common phenotypes 1, 2-1 and 2, and of the rare phenotypes 1 (Atkinson) and 2-1 (Atkinson). The electrophoretic and staining techniques are described in ref. 1.

relatively weak, but there is an intense component with a mobility similar to *g*, and a further intense component with a mobility greater than *g*. An even faster moving but extremely weak component is also probably characteristic of these phenotypes. This pattern of components was observed in three members of the family (Fig. 2). In one of them (I₁) it was associated with *a* and components typical of PGM 1. In the others (II₁ and I₂) it occurred together with components *a*, *b*, *c* and *d* which are characteristic of PGM 2-1.

Since the unusual pattern of fast moving components as observed in individuals from three successive generations of the same family, it seems likely that it is determined by an uncommon gene for which these individuals are heterozygous. This gene evidently segregates independently of the genes previously designated *PGM*¹ and *PGM*² since it appears to have been transmitted by I₁ to one but not the other of his non-identical twin daughters, both of whom had the *a*, *b*, *c* and *d* components typical of PGM 2-1, and must have received the *PGM*² gene from their mother.

The electrophoretic patterns characteristic of the 'Atkinson' phenotypes suggest that the unusual gene which is present causes a specific structural alteration in components *e*, *f* and probably also in *g*. Individuals I₁, I₂ and II₁ are presumably heterozygous for this gene and its common allele, and the observed patterns can be most simply explained if they are considered as arising from a mixture of components *e*, *f* and *g* determined by the normal allele present, and the altered counterparts of these components determined by the unusual allele. If the structural alteration causes a net decrease in positive charge, such that the altered component *e* now has a mobility similar to that of the usual component *g*, and the alteration to components *f* and *g* results in a similar change in net charge, then the observed pattern can be accounted for.

The pedigree and electrophoretic findings suggest that genes at two distinct and not closely linked loci both of which affect the structure of phosphoglucosmutase components are segregating in this family. We may designate the locus previously recognized as specifically affecting components *a*, *b*, *c* and *d* as *PGM*₁, and the locus which

Fig. 2 Pedigree of family (MRC 226) showing segregation of PGM phenotypes

Fig. 3. Diagram of starch gel showing PGM components observed in haemolysates from individuals of the common phenotypes 1 and 2, and the rare phenotypes 3-1, 3-2, 4-1, 4-2 and 5-2

specifically affects components *e*, *f* and *g* as *PGM*₂. The common allele at *PGM*₂ for which most individuals are homozygous may then be designated *PGM*₂¹, and the uncommon allele present in individuals with the 'Atkinson' phenotypes *PGM*₂². In these terms the genotype postulated for the phenotype PGM 1 (Atkinson) is *PGM*₁¹/*PGM*₁¹/*PGM*₂²/*PGM*₂², and the genotype corresponding to PGM 2-1 (Atkinson) is *PGM*₁¹/*PGM*₁¹/*PGM*₂¹/*PGM*₂¹.

In the course of family and population investigations in which PGM in more than 2,000 blood samples from different individuals has been examined, several further uncommon phenotypes have been identified. Five of these are illustrated diagrammatically in Fig. 3. In one family eight individuals with phenotype PGM 3-1 and two individuals with PGM 3-2 were observed. The pedigree suggested that these phenotypes represent heterozygotes for an uncommon allele *PGM*₁³ with *PGM*₁¹ and *PGM*₁², respectively. The allele *PGM*₁³ probably determines the formation of two new components one of which has a mobility slightly slower than *d*, and the other slightly faster than *e*. PGM 4-1 and PGM 4-2 were also encountered among a group of related individuals. There were in all six individuals with phenotype PGM 4-1 and two with PGM 4-2, and the segregation pattern suggested that they were heterozygotes for a further allele *PGM*₁⁴ with the common alleles *PGM*₁¹ and *PGM*₁², respectively. *PGM*₁⁴ probably determines the formation of two components, one of which has a mobility intermediate between that of *a* and *b*, and the other a mobility slightly greater than *c*. Both these new components and particularly the faster one were very weak by comparison with the *a* and *c* or the *b* and *d* components with which they occurred. It seems possible, then, that the rare homozygotes *PGM*₁⁴/*PGM*₁⁴ when identified will exhibit a marked reduction in level of PGM activity. The phenotype PGM 5-2 has so far been identified in only one individual and family data are not available. The PGM of this individual showed two new components, one of which had a mobility intermediate between *c* and *d*, and the other a mobility intermediate between *d* and *e*. Components *b* and *d* were also present, and by analogy it was considered likely that the two new components were determined by an uncommon allele *PGM*₂³ which in this individual occurred in heterozygous combination with *PGM*₂¹. In each of the new phenotypes PGM 3-1, PGM 3-2, PGM 4-1, PGM 4-2 and PGM 5-2, the *e*, *f* and *g* components were apparently not affected and one may suppose that the individuals concerned were all homozygous for *PGM*₂¹. Full details of these family investigations will be published elsewhere.

We are grateful to Dr. J. H. Edwards for sending us samples from the family in Fig. 2.

ANTHROPOLOGY

Hair Colour of the Population of Tristan da Cunha

As a result of the volcanic eruption on Tristan da Cunha in 1962 some 268 islanders were evacuated to the United Kingdom. During their stay in this country many of them agreed to co-operate in a number of investigations concerning their physical condition and characteristics organized by the Medical Research Council. Their pigmentation was examined as part of this programme; I was concerned with hair colour.

People the world over show a certain reluctance to part with quantities of their head hair sufficient for detailed laboratory investigation of pigmentation. In this respect the Tristanites were no exception, and only some 131 individuals provided useful quantities of hair.

A number of investigations of hair pigmentation including those of Reed¹, Sunderland² and Barnicot³ have utilized spectrophotometric data including, in particular, percentage reflectance values, as means of denoting brightness and hue. These procedures involving precise quantified information introduced a measure of objectivity into such studies which had been less evident in previous work. Thus Reed¹, for example, denoted redness by the *R* statistic with $R = 100(y_{530} - 0.243y_{400})/Y_{650}$ while Sunderland² used size (*Q*), shape (*P*) and both combined (*L*) statistics in order to characterize the percentage reflectance curves for the hair samples which he studied.

It was hoped that sufficient hair would have been available from the Tristanites to allow the measurement of percentage reflectance values and subsequent statistical analysis of the data, as was possible in the enumerated studies. However, the quantities of hair available disallowed the use of spectrophotometric techniques. The only, fairly satisfactory, alternative means of characterizing this pigmentary variable appeared to be the use of the *Haarfarbentafel nach Fischer-Saller*. This consists of thirty tufts of human hair ranging in colour from very blond (Weiss blond), designated by the letter *A* at one extreme, to the darkest shades of hair (*Braun schwarz*), designated by the letters *U-Y* at the other, together with the intermediate categories *Hell blond* (*B-E*), *Blond* (*F-L*), *Dunkel blond* (*M-O*) and *Braun* (*P-T*) in order of increasing darkness. The Roman numerals I-IV cover a range of red hair shades; V and VI the red-blond range. Hair specimens are matched with these standards and the colours characterized accordingly. In this investigation, the matching was carried out independently by two people, working in good daylight. Their agreed results are summarized in Table 1.

None of the lighter shades of hair colour (*A-L*) is represented in this population, and only three individuals have hair as light as the *Dunkel blond* category. In fact, the great majority of the islanders have dark brown-black hair, the only dramatic exception being the unique vividly red-haired individual. Traces of red hair, usually single red hairs among predominantly brown-black hairs, are occasionally visible in this population.

Table 2 shows the relationship between hair colour and sex.

There do not appear to be any significant sex differences. Therefore, taking both sexes together, Table 3 shows the relationship between hair colour and age.

Table 1. FISCHER-SALLER HAIR COLOUR DESIGNATIONS FOR THE TRISTAN DA CUNHA SAMPLE

Fischer-Saller designation	Number of specimens	Fischer-Saller category
M	1	Dunkel blond
N	1	
O	1	
P	0	
Q	1	Braun
R	0	
S	4	
T	4	
U	8	Braun schwarz
V	9	
W	13	
X	46	
Y	42	Rot
Z	1	
Total	131	100.00%

Table 2. HAIR COLOUR AND SEX

Fischer-Saller category	(No.)	Males (% of total)	Females (No.)	(% of total)
Dunkel blond	2	3.12	1	1.49
Braun	3	4.69	6	8.96
Braun schwarz	59	92.19	59	88.06
Rot	0	0.00	1	1.49
Total	64	100.00	67	100.00

Table 3. HAIR COLOUR AND AGE

Age group (years)	Fischer-Saller categories								Total
	<i>Dunkel blond</i>		<i>Braun</i>		<i>Braun schwarz</i>		<i>Rot</i>		
	No.	% Total	No.	% Total	No.	% Total	No.	% Total	
0-15	2	4.3	7	15.2	38	78.3	1	2.2	48
16-30			1	3.3	29	96.7			30
31-45					26	100.0			26
46-60					15	100.0			15
61-81					8	100.0			8
	2	1.6	8	6.4	114	91.2	1	0.8	125

It is well known from a number of investigations including those of Cowie and Penrose⁴ and Sunderland² that hair colour darkens with age. In the present results it is interesting to note that the fairest people, in the *Dunkel blond* category, are in the youngest age bracket (0-15 years) and that the *Braun* category likewise is found only among individuals aged 30 years and less. Again, red hair fades with increasing age. This was clearly demonstrated by Reed¹ and by Sunderland². Among red-haired individuals, the *R* statistic increases in value with the years; that is, their red hair becomes less so. Here, the only red-haired individual is in the 0-15 age category, and it may well be that at a more advanced age this individual's hair may become much less red or even predominantly brown. All individuals aged 31 years and over have *Braun schwarz* hair.

Quite evidently, this population is predominantly darkly pigmented. Some of the early settlers on Tristan were north-west Europeans, including Glass, Swain and Green, while Rogers and Hagan were American. However, others were from predominantly darker populations, including Repetto and Lavarello from Italy, five women from St. Helena who arrived on the island in 1827 and who are reported to have been of mixed European and 'coloured' parentage and also William Glass's wife from the Cape Coloured population of South Africa. These origins summarized by Harris *et al.*⁵ and the subsequent hybridization on Tristan adequately account for the hair pigmentation characteristics of the islanders.

Any estimate of the quantitative contributions of the Europeans, Americans, Italians, St. Helena people and Cape Coloureds (and possibly other groups also) to this population is fraught with difficulty. So far, even the initial step of comparing the hair colour of the Tristanites with the populations listed is impossible since hair colour data, particularly using the *Haarfarbentafel nach Fischer-Saller*, is not available for those groups.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, October 25

- *LASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP the Wellcome Building, Euston Road, London, N.W.1, at 3 p.m.—Symposium on "The Changing Face of Reinforced Plastics".
- *LASTICS INSTITUTE, PLASTICS PROPERTIES DISCUSSION CIRCLE (at the Mandeville Hotel, Mandeville Place, London, W.1), at 3 p.m.—Mr. E. B. Sisson: "Flow Behaviour of Molten Polymers".
- *ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), 5 p.m.—Prof. E. G. Bowen: "The Welsh Colony in Patagonia".
- *BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Council Room of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—F. W. Gibbs: "Gunpowder Priestley and Dictionary Johnson".
- *INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), 5.30 p.m.—Sir John Cockcroft, O.M., F.R.S.: "Competitive Nuclear War".
- INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.E.—E.R.E. COMPUTER GROUPS (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. W. J. Poppelbaum: "Opto-Electronics".
- INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT ASSOCIATION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. J. T. Bull: "C. Traction Power Supplies" (Chairman's Address).

Tuesday, October 26

- SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (at 14 Belgrave Square, London, S.W.1), at 10 a.m.—Meeting on "Land Restoration".
- UNIVERSITY OF LONDON (at Imperial College of Science and Technology, London, S.W.7), at 1.30 p.m.—Mr. E. F. Schumacher: "Levels of Being: What is Man?".
- INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. J. V. Bartlett, Mr. T. M. Noskiewicz and Mr. J. A. Ramsay: "Soft Ground Tunneling for the Toronto Subway".
- INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Emission from Conductors into Dielectrics" opened by Dr. T. J. Lewis.
- UNIVERSITY OF LONDON (at Queen Elizabeth College, Campden Hill Road, London, W.8), at 5.30 p.m.—Prof. H. J. B. Atkins: "Charles Darwin and his Influence" (Inaugural Lecture).
- UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. A. S. V. Burgen: "The Salivary Glands". (Second of fifteen lectures in "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).
- INSTITUTION OF MECHANICAL ENGINEERS, MANUFACTURE AND MANAGEMENT GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Make Your Workshop Buzz with a Machine Loading Computer Programme".

Wednesday, October 27

- INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 4.30 p.m.—Annual General Meeting. Prof. M. S. Blackett, C.H., F.R.S.: "The Continental Drift" (Duke of Edinburgh's Lecture).
- INSTITUTE OF FUEL (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 5.30 p.m.—Prof. G. J. Hills: "The Electrochemistry of Deposits of Inorganic Constituents of Fuels at High Temperatures".
- INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. H. Norman G. Allen, C.B.E.: "Ex Opera et Industria" (Presidential Address).
- SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP—NUTRITION PANEL (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Prof. J. Yudkin: "Appetite Control".

Thursday, October 28

- UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. C. Vita-Finzi: "The Mediterranean During the Ice Age".
- UNIVERSITY OF LONDON (at Bedford College, Regent's Park, London, N.W.1), at 5.15 p.m.—Prof. Monica M. Cole: "Biogeography in the Service of Man (with particular reference to the Underdeveloped Lands)" (Inaugural Lecture).
- INSTITUTE OF PETROLEUM, EXPLORATION AND PRODUCTION GROUP (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. B. Benthall: "The History of Exploration and Development of Oil in Burma".
- UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. Eleanor Zaimis: "Immunological Sympathectomy". (Third of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).
- INSTITUTION OF MECHANICAL ENGINEERS, LUBRICATION AND WEAR GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Temperature Limits of Liquid Lubricants".
- TELEVISION SOCIETY (joint meeting with the Institution of Electrical Engineers and the Institution of Electronic and Radio Engineers, at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 6 p.m.—Dr. W. Bruch: "The P.A.L. Colour Television System".

Friday, October 29

- SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMICAL METHODS GROUP (at the Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 4.30 p.m.—Meeting on "Microchemistry—Past, Present

and Future". Speakers: Prof. R. Belcher, Mr. C. Whalley and Prof. C. L. Wilson.

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. H. H. Watson: "Some Recent Developments in Ultra-High-Vacuum Technology".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Baroness Jane van Lawick-Goclad: "Infancy, Childhood and Adolescence in the Wild Chimpanzee".

Saturday, October 30

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. A. Robinson: "Natural History of a Landslide".

Monday, November 1

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 9.30 a.m. and 2.15 p.m.—Colloquium on "HS 303 (Early Bird) and the Post Office Earth Station at Goonhilly".

PLASTICS INSTITUTE, PLASTICS PROPERTIES DISCUSSION CIRCLE (at the Mandeville Hotel, Mandeville Place, London, W.1), at 3 p.m.—Mr. D. R. Reid: "Ageing".

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Dr. D. A. Price Evans: "Genetics and Drug Idiosyncrasy".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. Ralph Audy (U.S.A.): "Red Mites and Typhus. I. Scrub-itch and the Ecologist".

UNIVERSITY OF LONDON (in the Chemistry Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. J. Millen: "Molecular Measurements" (Inaugural Lecture).

INSTITUTION OF MECHANICAL ENGINEERS, MEDICAL ENGINEERING WORKING PARTY (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Informal Discussion on "The Doctor's View of Engineering: The Engineer's View of Medicine".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"The Island" (film with introduction by Prof. C. A. Fisher).

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dame Kathleen Lonsdale, D.B.E., F.R.S.: "Crystallography as a Research Tool in Chemistry" (Jubilee Memorial Lecture).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

INSPECTOR GRADE III (Scientific Officer, not over 35, with a recognized first- or second-class honours university degree in which zoology was taken as a major subject) in THE DEPARTMENT OF LANDS, Dublin, for work in connexion with the development of game resources—The Secretary (S.18), Civil Service Commission, 45 Upper O'Connell Street, Dublin, 1, Republic of Ireland (October 26).

SENIOR SCIENTIFIC OFFICER or SCIENTIFIC OFFICER (with a Ph.D. or good honours degree with equivalent research experience in genetics or plant breeding) for breeding work and study of breeding methods with vegetables—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (October 29).

CHAIR OF ORGANIC CHEMISTRY—The Registrar, University of Kent at Canterbury, Canterbury, Kent (October 30).

LECTURER or ASSISTANT LECTURER in SOCIOLOGY—The Secretary, The University, Aberdeen (October 30).

LECTURERS IN ENGINEERING MATHEMATICS—The Registrar, The University, Newcastle upon Tyne, 2 (November 1).

TUTORIAL STUDENT in the DEPARTMENT OF ELECTRICAL ENGINEERING—The Registrar, King's College, Strand, London, W.C.2 (November 1).

BIOCHEMIST (with an honours degree in biochemistry and some research experience or a Ph.D.) in the PSYCHOSOMATIC RESEARCH UNIT, DEPARTMENT OF PHYSIOLOGICAL MEDICINE (University of Glasgow), to assist with the investigation of aspects of endocrine function in certain bodily illnesses in human subjects—The Director of the Psychosomatic Research Unit, Southern General Hospital, Glasgow, S.W.1 (November 5).

LECTURER in the DEPARTMENT OF ZOOLOGY, University of Tasmania, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 10).

LECTURER (with an honours degree in electrical engineering) in ELECTRICAL ENGINEERING at the University of Tasmania, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 10).

READER in IMMUNOLOGY at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 10).

LECTURER/ASSISTANT LECTURER (with at least a good honours degree with suitable teaching and research experience, and preferably specialized in some branch of solid state physics) in the DEPARTMENT OF PHYSICS, University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, November 15).

LECTURER or ASSISTANT LECTURER in GEOGRAPHY at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 15).

LECTURER (with a veterinary qualification) in VETERINARY MEDICINE—The Secretary, Trinity College, Dublin, 2, Republic of Ireland (November 15).

LECTURER (preferably with research interests in astrophysics, optical astronomy, radio astronomy or plasma physics) in PHYSICS at the University of Tasmania, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 19).

SENIOR LECTURER (preferably with registrable veterinary qualifications) in VETERINARY PHYSIOLOGY in the DEPARTMENT OF VETERINARY PRECLINICAL SCIENCES, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (November 26).

DIRECTOR OF THE MARINE BIOLOGICAL LABORATORY AT MILLPORT, Scottish Marine Biological Association—Dr. C. M. Yonge, C.B.E., F.R.S., 13 Cumin Place, Edinburgh, 9 (November 30).

SENIOR LECTURER or LECTURER (with a degree in mechanical engineering, preferably at honours level, of a recognized Commonwealth University, together with either experience in industry or research and teaching experience at university level) in **MECHANICAL ENGINEERING** at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 30).

LECTURER or SENIOR LECTURER in CHEMICAL PATHOLOGY, University of Otago Medical School, Dunedin, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, December 15).

CHAIR OF PHYSIOLOGY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (January 4).

AGRICULTURAL CHEMIST (national of the United Kingdom or the Republic of Ireland, with a second-class honours degree in agricultural chemistry or chemistry, plus at least two years' postgraduate training or experience in soil science) in Uganda, for research work on soil fertility problems connected with tropical rotations, manures and fertilizers—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/183/022.

ASSISTANT CONSERVATOR OF FORESTS (national of the United Kingdom or the Republic of Ireland, under 40, with a degree in forestry) in Kenya, for work in connexion with the administration and technical direction of a forest division—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 324/95/01.

BIOLOGIST (national of the United Kingdom or the Republic of Ireland, between 24 and 35 years, with an honours degree in zoology and postgraduate experience in animal ecology) in Tanzania, to investigate the ecology of game animals in the woodland areas—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 275/173/01.

BIOLOGIST (preferably with a Ph.D. or medically qualified, and interests or experience in the problem of graft versus host reaction, immunological tolerance and mitotic synchronization) for a research post in a unit working on trophoblastic tumours and leukaemia in the Charing Cross Hospital Group—Dr. K. D. Bagshawe, Edgar Laboratory, Fulham Hospital, London, W.6.

CHEMICAL or BIOCHEMICAL TECHNICIAN to assist in research on muscle disease—The Secretary, Institute of Neurology, The National Hospital, Queen Square, London, W.C.1.

DEMONSTRATORS (2) in the DEPARTMENT of PHYSICS for laboratory demonstrating work and assistance with student tutorials—The Registrar, University College of Wales, Aberystwyth.

LECTURER or ASSISTANT LECTURER in THEORETICAL PHYSICS—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey.

LECTURER (well qualified academically with postgraduate experience in industry and/or teaching) in **PHYSICAL CHEMISTRY** to teach to B.Sc. and Grad.R.I.C. Part II level—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent.

OIL PALM AGRONOMIST (national of the United Kingdom or the Republic of Ireland, with a degree in agriculture and postgraduate training, preferably with previous experience as an agronomist) in Sarawak, to open up and establish a new experimental station, mainly concerned with oil palm and other crops new to Sarawak, for example, cocoa and hemp—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/155/08.

RESEARCH ASSISTANT or RESEARCH STUDENT to work in the Department of Physics with a small group investigating the application of existing and novel techniques of geophysical prospecting to archaeology—The Registrar, Ref. 126Y/E, Bradford Institute of Technology, Bradford, 7.

RESEARCH FELLOW (with a higher degree and preferably experience in the field of semiconductor physics, technology or chemistry) in the SCHOOL of PHYSICS, to work on new direct-gap semiconductor compounds for use as semiconductor lamps, lasers and Gunn devices—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol, 7, quoting Ref. CST 65/98.

RESEARCH OFFICER (Virologist) (national of the United Kingdom or the Republic of Ireland, with an honours degree in botany or agricultural botany and experience in plant virology) with the East African Common Services Organization, to study virus diseases affecting agricultural crops and to help with the scientific supervision of the East African Plant Quarantine Station—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting RC 213/214/011.

SENIOR LECTURER in SOCIAL ANTHROPOLOGY; a SENIOR LECTURER or LECTURER in PHILOSOPHY; a LECTURER in PSYCHOLOGY; and a LECTURER in ENTOMOLOGY at the University of Auckland, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

SOIL CONSERVATION ENGINEER (national of the United Kingdom or the Republic of Ireland, with a second-class degree in agricultural engineering, or a degree in soil conservation, or a degree in civil engineering and soil conservation, and preferably experience in soil conservation) in Uganda, to carry out soil conservation measures on projects, to check layouts, to train field staff and to collect data and prepare a handbook—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/183/020.

SOIL SURVEY OFFICER (national of the United Kingdom or the Republic of Ireland, with an honours degree in either natural science, agriculture or geography, with, if possible, postgraduate training or experience in soil science) in Uganda, to carry out soil surveys as a member of a land planting team working on the development of group farms—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/183/019.

THE CROFT PARALLEL GRINDER

This parallel grinder has been specially designed and constructed for the Palaeontologist

A Brachiopod or similar fossil is mounted in plaster, and attached to the specimen holder with Cerosene wax. The machine then rotates on three ball bearings on a restricted parallel plane, and the micrometer head, which is graduated in 100ths of millimetres, can be set to grind off a requisite amount.

For full information write or telephone

Through various stages of grinding, the fossil is washed, and the structure recorded by means of drawings, photographs or cellulose acetate peels. Thus the complete internal structure of any fossil can be recorded every 1/8th millimetre, or less if required.

The motor driven version of this machine can also be used for controlled grinding of thin specimens and has been successfully applied to the manufacture of thin sections of teeth, bone and gall stones.

RETHINKING CIVIL SERVICE POLICY

TO the scientist and technologist one of the most interesting features of the sixth report from the Estimates Committee for the Session 1964-65*, dealing with recruitment to the Civil Service, is the section which considers the needs of the Civil Service not simply for administrators but for specialists and their role in the service. This is seen not merely through the eyes of the Civil Service itself in the person of Sir Laurence Helsby, head of the Home Civil Service, Sir William Armstrong, Joint Permanent Secretary to the Treasury, and Sir Richard Way, Permanent Secretary to the Ministry of Aviation, for example, but also through those of outside witnesses, including Prof. W. J. M. Mackenzie, Mr. D. N. Chester, Mr. B. J. Holloway and the Institution of Professional Civil Servants. As the Estimates Committee observes, the recruiting methods used depend as much on the assumptions and attitudes about the kind of people required in the Service, the approach to their work which would be required of them, and the division of functions proper within the Service, as on the size and character of the total employment market. It was, therefore, concerned to explore these assumptions and attitudes since they determine the appearance and mode of operation of the Civil Service, both as it is to-day and as it will be during the next generation.

Sir Laurence Helsby believes that there would continue to be a small administrative class, remaining separate from the general service class responsible for the day-to-day run of administration and responsible for somewhat specialized functions which seldom had any precise counterpart in outside organizations—at least below board-level. Staffing at this level called for a particular type of man and for qualities which, he believed, could not be effectively shown in an advertisement, but he did not think that this approach led to a Service which was poised to change. Sir William Armstrong expressed a similar view and, in regard to mobility, thought it was unlikely to reach a point when, at the end of his life, a man could say, "I have spent as much time out of the service as in it". The distinction between the man whose basic career is the Civil Service but who goes out from time to time and the man who is really temporary would remain. He did not deny that there was any need for a reappraisal of the pattern of the Civil Service, and Sir Laurence Helsby suggested that it would be well to wait at least a year before making a broader enquiry into the organization, recruiting and structure of the Civil Service. However, he did agree with the suggestion that such a review would be desirable in spite of the probability that developments in the structure of Government would be rapid for ten years to come.

Sir William Armstrong directed attention to the limitations of the use of techniques such as cost-benefit analysis which were placed by the number of people familiar with these techniques both in the departments concerned and elsewhere in the Government service, local authorities and the nationalized industries. This is accordingly a question of the special trained manpower, and Sir William maintained that the really pressing need was for more specialists, particularly as economic advisers—though in the long term it was

probable that the Service would develop its own brand of expert in what might be called 'Government economics'. Here the Centre for Administrative Studies might help, but other witnesses saw a danger of rigidity in such a development.

Sir Richard Way and Sir Eric Roll, the Permanent Under-Secretary of State at the Department of Economic Affairs, made some interesting observations on the part played by the scientist and other specialists and their relation to administrators. Sir Richard was emphatic that a scientist equipped to do administrative work would not be deterred from entering the scientific grade by the prospects of promotion. However, he thought that for the position of scientific officer the Service required a man competent for a particular piece of research, without special personal qualities, whereas the administrative class Civil Servant in the higher grades should have had wide experience. Scientists destined for more senior posts were helped to widen their experience while remaining specialists. When Sir Richard had encouraged scientists to enter the administrative class he had found that they had usually wished to remain where they were; in his view it was a wholly false picture to imagine that every scientist wanted to become an administrator. The distinction between administrators and scientists was not a hindrance to recruiting. On the contrary, many young scientists who entered the Service would be deterred by the abolition of this distinction. Nor did he think that scientists were deterred by the thought that administrators were amateurs; rather the scientist would regard the administrator as being highly professional in the field he had chosen.

Sir Eric Roll suggested that the relation of economists to administrators was rather different simply because the tasks of Government had a much greater affinity with the field of interest of economists and other social scientists. Nevertheless, though the division between economists and administrators was not so easily defined as that between nuclear physicists and biochemists and administrators, the tasks of the administrator differed in kind from those of the economist. Pointing out that 43 per cent of the administrators in the Department of Economic Affairs had degrees or other qualifications in economics, Sir Eric added that no difficulties from rigid procedures had arisen in obtaining specialized staff. Lack of flexibility had had no real effect on the Department's recruitment possibilities.

These views, however, were not unchallenged in the evidence. The memorandum from the Institution of Professional Civil Servants expressed the unanimous view that if the professional and similar specialists classes were to be given managerial responsibility and if this were to become known, it would have an important and beneficial effect on recruitment. The professional classes, at present, have a strong feeling that they are not given full and proper scope to discharge the responsibilities that they are equipped to carry. Even propaganda in the schools would be more effective if it could be shown that specialists in general were not at a disadvantage in terms of responsibility and advancement to the highest posts. The evidence of the Ministry of Aviation in regard to the transfer of scientists to the administrative class was questioned as inaccurate. It was pointed out that experience in industry shows that transfers to broaden

* Sixth Report from the Estimates Committee together with the Minutes of the Evidence taken before Sub-Committee E and Appendices, Session 1964-65—Recruitment to the Civil Service. Pp. xxxviii+269. (London. H.M.S.O., 1965) 26s. net. (See also *Nature*, 208, 311; 1965)

experience are neither unpopular among young scientists nor a deterrent to recruitment. Mr. D. N. Chester, however, suggests that the evidence indicates that science graduates with first-class degrees prefer to continue with scientific work rather than take administrative or managerial posts. Certainly, he doubts whether this will change when the output of scientists is greatly increased. Nor has it yet been proved that those with a scientific training have a particular aptitude for the higher levels of administration.

The Institution of Professional Civil Servants submits that for the specialist Civil Service the Government's employment policy should rest on three main principles. It should exploit to the full the training and talents of its scientists, technologists and technicians and ensure that there is full employment in terms of the quality of work they are given to do. It should make clear that specialists are full and equal partners with other staff, and that they have an equal opportunity to promotion to the highest posts. It should offer pay and careers which demonstrate that scientists, technologists and technicians are no longer regarded as inferior or second-rate.

In all this evidence there is little that is not to be found in the Barlow Report on scientific staff which was released almost twenty years ago. The Estimates Committee comments that the picture which emerges from this examination is one of considerable development in the patterns and traditions of the Civil Service and of readiness for further development—basically, however, development within an established framework of assumptions. There does not appear to have been any fundamental questioning of the basic structure, and the Estimates Committee finds it hard to accept that the task of Government justifies the unique significance attaching to the administrative class and that only a select few are fitted to undertake this work. It also questions the assumption that all a specialist wants to do on leaving university is to work within his specialized subject. In this connexion, the Committee directs attention to the evidence of Mr. P. F. Nind, of the Shell International Petroleum Co., Ltd., that relatively few among specialist technical staff desire promotion in their own narrow function, whereas many wish to broaden their experience and run small companies elsewhere. This, as Mr. Nind remarked, is entering general management.

While the Estimates Committee welcomes the changes that have already been made or are planned to increase the flexibility of the Civil Service and its ability to undertake new tasks, it considers, nevertheless, that this aspect needs further and much more systematic study. Accordingly, this is one of the considerations which could well be subjected to further enquiry—in particular, the actual tasks undertaken and those that should be undertaken by the administrative class in the near future. The Committee discusses, moreover, recruitment to the Scientific Civil Service in a further section of its report, and here there are some observations that throw further light on the evidence given by Mr. Nind.

The experience of the Civil Service has been that young scientists prefer to become members of a particular team or establishment, rather than to join the Scientific Civil Service as such. This was confirmed by Mr. B. J. Holloway, secretary of the Appointments Board of the University of Manchester, who in expressing the view that the Scientific Civil Service was the section of the Civil Service which had really faced the problems of competitive recruitment—a view which the Estimates Committee endorsed—remarked that to the fresh graduate

it was a more stimulating thought to work, say, at Farborough than to apply to the Civil Service Commission for establishment as a scientific officer. Nevertheless, although Sir Richard Way fully recognized that establishments like Farnborough and Malvern are far more vital and attractive than the Ministry of Aviation as such, his other observations indicate how far some of the senior officers in the Civil Service still are from understanding the scientific life and even the implications of Sir Alexander Barlow's Report.

Rejecting the suggestion that older scientists who have passed their creative years might be transferred to administration, Sir Richard characterized as absurd "the idea that a worn-out scientist can, as an afterthought, come in as an administrator". This is a complete misunderstanding, if not misrepresentation, of how to use to the maximum public advantage the skill and experience of trained manpower. The large industrial firms have long recognized that in research, as in art, creative power are at their peak in youth but tend to decline in middle life; experience, on the other hand, grows and may be used to advantage in many ways. It is here that the Civil Service appears to have fallen behind industrial and commercial practice, for example, and this may well contribute to the unsatisfactory overall situation for scientists, though the general shortage of good graduates and competition are clearly contributory factors. It may be noted that Sir Laurence Helsby in his evidence admitted that mobility in the Service was not so high as he would like it to be, and was clearly not opposed to the use of scientists in administration. The Estimates Committee concludes this section of its report with the remark that, quite apart from the importance of providing good promotion prospects for the scientist, the man with the scientific or mathematical background was more than ever needed in management to-day, in view of the importance of the ability to quantify problems: this is at least as true of public administration.

In discussing recruitment for modern needs, in the final section of its report, the Estimates Committee draws together the evidence which impressed it most with the need for a thorough examination of the problems of recruitment to the Civil Service. All the evidence shows that the Civil Service and the Civil Service Commission are aware that not all the requirements of the Service are being met and that efforts are being made to meet them. Nevertheless, the Estimates Committee believes that the measures taken have not yet been extended to a re-examination of the structure of the Service and other issues underlying recruitment. In three areas in particular detailed examination might be expected to lead to proposals for change.

The first is in the extent of mobility, both within the Service and between the Service and other occupations, including consideration of other means of acquiring wider experience and keeping the Service in touch with the developing community. The second is the need for professional training and the means available for acquiring a knowledge of specialist techniques at the beginning and in the course of a career. The third is the urgent need to examine the supply of qualified manpower on which the Civil Service is to draw. It is a fallacy, as the Estimates Committee remarks, to suppose that, in the long term, the supply of qualified people in any one field is fixed, because the recruiting policies of the Government inevitably affect the total supply. However, in these last two areas, it can be added that enquiry could lead to suggestions for the wise and efficient use of trained manpower,

such as are implicit, though not explicit, in the memorandum from the Institution of Professional Civil Servants.

Research and public discussion on these important developments could contribute to what Prof. W. J. M. Mackenzie termed "the shaping of a public doctrine about the place of the Civil Service in modern Britain". This, he thought, would be a most valuable result of the appointment of a Royal Commission such as he had suggested at the end of his evidence. This Commission should be a relatively small one, of independent standing, empowered to recruit its own research staff, and not placed, as was the Priestley Commission, in a situation which demanded an urgent and specific report. Mr. D. N. Chester also supported the appointment of a Royal Commission, provided a suitable chairman and membership could be found, and the Commission was adequately staffed and empowered to arrange for research. He suggested that it should be established in 1967, thus giving adequate time for preparatory work and discussion.

This date accords with the views expressed in evidence by Sir William Armstrong and Sir Laurence Helsby; the latter, however, suggested that there was great advantage in having a review of the Service undertaken by a group of people, some of whom, in any event, had had direct experience of its working. Moreover, such an internal committee of officials would have access to information which could not easily be made available even to a Royal Commission. A Royal Commission, however, has advantages in authority and in the publicity in which its enquiries are usually conducted. The Estimates Committee was impressed by the desirability of a preliminary internal enquiry and also emphasizes the value of well-directed and independent research. Its recommendations appear to be in accordance with the balance of the evidence. They are: (1) appointment of a committee of officials, aided by members from outside the Civil Service on the lines of the Plowden Committee, to initiate research on, to examine and report on the structure, recruitment and management of the Civil Service; (2) that the Government should review the position immediately on receipt of the report, and report to Parliament the action it proposes to take, appointing forthwith a Royal Commission if further enquiry by such a Commission is then found to be necessary. Meanwhile the Estimates Committee's report should stimulate preliminary discussion and the Parliamentary and Scientific Committee should be able to ensure that the whole question is not side-tracked, whether on pretext of Parliamentary time or any other excuse.

Dictionary of Organic Compounds

The Constitution and Physical, Chemical and other Properties of the Principal Carbon Compounds and Their Derivatives, together with Relevant Literature References. Edited by Dr. J. R. A. Pollock and Dr. R. Stevens. Fourth, completely revised, enlarged and re-set edition. Vol. 1: A-Chlor. Pp. xxx+1-588. Vol. 2: Chlor-Dim. Pp. 589-1230. Vol. 3: Din-Iza. Pp. 1231-1976. Vol. 4: J-Phloi. Pp. 1977-2736. Vol. 5: Phlor-Zym. Pp. 2737-3282. First Supplement 1965. Pp. 207. (London: Eyre and Spottiswoode (Publishers), Ltd; and E. and F. N. Spon, Ltd., 1965.) £100 the set.

THE *Dictionary of Organic Compounds* requires no introduction to organic chemists, to whom it is always known as "Heilbron's Dictionary", for the late Sir Ian

Heilbron was the moving spirit at its initiation and guided it vigorously through its subsequent development until well into the preparation of the present edition.

Workers in neighbouring sciences who may occasionally require information about specific organic compounds may, however, welcome a brief indication of its nature and contents. The first edition appeared during 1934-1937 in three volumes, to be followed during 1943-1953 by the second and third editions, the latter appearing in four volumes. The editors of the first edition accepted the formidable task of selecting from the vast number of recorded organic compounds those to which they considered organic chemists would most frequently want to refer. These were listed in alphabetical order, with their molecular formulae, structural formulae when desirable, and physical properties: this information was followed by a list of the main derivatives of the compound, and a final list of original references. This pattern of the *Dictionary* remains unchanged. The volumes, therefore, provide a rapid and reasonably up-to-date reference to a very large number of compounds. Information about other organic compounds may be sought either in *Beilstein's Handbuch*, which by virtue of its size labours along several years out of date but provides exhaustive treatment, or in the many indexes, annual, five-yearly and decennial, of *Chemical Abstracts*.

The new fourth edition has been completely revised, enlarged to five volumes and very handsomely re-set and bound: the type now adopted gives a very clear and attractive appearance to the pages. The edition includes material obtained by searching *Chemical Abstracts* up to 1962, and by a review of the major chemical journals up to the end of 1963. It is stated to "include all major natural products, pharmaceuticals, pesticides and similar groups of applied chemicals"; natural products, therefore, now appear prominently. It is accompanied by a supplement as a separate volume, which contains new material published in and before 1964. This supplement represents a new feature, for it is the first of a series of annual supplements, of which the fifth will be a cumulative edition containing the material of that year and of the preceding four years: the annual supplements will then continue until the tenth number, which will again be a cumulative volume containing the material of the immediate past five years. (Librarians should note that there is a subscription scheme available for the purchase of these supplements under which the cumulative volumes can be purchased at half-price.)

This fourth edition is about 40 per cent larger than the third, and the considerable increase in the number of entries has largely coincided with various changes of nomenclature: since the names of the compounds form their own index, the editors had to ensure that any compound could be readily found. Many compounds have trivial or common names which are very widely used: in such cases the editors have used their discretion in deciding whether the compound shall be entered in detail under its trivial or its systematic name; since in almost all such cases cross-references (each in its appropriate alphabetical position) are given, no difficulty should arise. Drugs and pesticides in this respect fall into a special category. Since almost all modern drugs, including antibiotics, are known to manufacturers, to the medical profession and to pharmacists and chemists by trade-names (and systematic names would be exceedingly cumbersome), the *Dictionary* uses the names approved by the British Pharmaceutical Commission of the General Medical Council. Similarly, pesticides (although often of more simple structure) are entered under the common names recommended in the *British Standards List B.S. 1931* (1961). Many proteins fortunately now have structure 'names' based on generally accepted conventional abbreviations.

The main difficulty arises from the fact that many systematic names, and also the numbering of (in par-

ticular) many heterocyclic systems, have been changed from time to time by the nomenclature committees of the International Union of Pure and Applied Chemistry; the last set of rules (now fairly widely accepted) were published in 1957. The introduction to Volume 1 summarizes "a few of the outstanding basic rules of nomenclature from the I.U.P.A.C. 1957 rules" in $8\frac{1}{2}$ pages. These rules are, however, often complex and detailed, and cannot be readily understood and applied without ample structural formulae and examples for illustration. The space given in the introduction is insufficient for this purpose, but a reasonably full account would clearly occupy far too much space. The reader could well be referred to the *Handbook for Chemical Authors* (Chemical Society Special Publication No. 14, 1960) by Dr. R. S. Cahn and Dr. L. C. Cross, where the 1957 rules are explained and discussed in detail. It also contains the highly specialized rules agreed in 1952 between the committees of the Chemical Society and the American Chemical Society for organophosphorus compounds, an increasingly common group of compounds to which the *Dictionary* gives little attention.

Two points regarding the presentation may be made. It has already been stated that under the name of the 'parent' compound is a list of its chief derivatives and also a list of references. Now it often happens that a reader is consulting the *Dictionary* to obtain information on one specific derivative: the *Dictionary* usually provides for solid derivatives the melting-point and the solvent for crystallization, and the reader, requiring more information, is given no guidance as to which of the references record this compound, and he has therefore to work steadily and laboriously through them. For example, under "Phenylacetic acid" (p. 2666) there are nearly thirty derivatives listed, followed by eleven references in various journals: the reader who ultimately finds the required information in the eleventh reference will be weary and rather exasperated. This disadvantage could have been overcome, for example, by placing small superscript letters alphabetically above each reference: the names of the derivatives would then each carry the superscript letter of the reference in which they are to be found. This could easily have been done in the early days of the *Dictionary*, but would now involve much tedious work.

The second point, of lesser importance, is that the elements in the molecular formulae "are given in the order C,H,O,N,Cl,Br,F,S,P with any others following in alphabetical order" (Volume 1, p. xi). This is quite clear, but slightly old-fashioned. The modern formulae indexes of *Beilstein*, *Chemical Abstracts*, etc., all adopt the more simple system of giving the elements in the order C,H, with all the remainder following in alphabetical order.

One minor point. One solvent used for crystallization is frequently named 'petroleum ether' or 'pet. ether'. This term is a relic of the old days when a set of solvent bottles bearing permanent titles normally included 'sulphuric ether' and 'petroleum ether'. The first title has long been obsolete and the second should rapidly have followed it: certainly no organic chemist should call a hydrocarbon an ether. The *Dictionary* also uses the rather old-fashioned alternative 'ligroin': the use of 'petroleum', possibly abbreviated to 'petrol', throughout would surely have been preferable?

These points, however, do not seriously detract from the very great value of the immense amount of classified information which this fourth edition contains—information which with the Supplement 1965 is based on more than 40,000 entries. The heavy labours of the editorial staff, moreover, receive deservedly excellent presentation at the hands of the printers. Had Sir Ian Heilbron survived, this edition would certainly have been a source of great pride to him.

F. G. MANN

W. M. W. HAFFKINE

The Brilliant and Tragic Life of W. M. W. Haffkine
Bacteriologist. By Selman A. Waksman. Pp. 87 + 3 plates
(New Brunswick, N.J.: Rutgers University Press, 1964.
3.75 dollars.

THE author of this book visited the Haffkine Institut in the year 1962. While the name of Haffkine resound in the heart of every bacteriologist, his life is an interesting adventure in the early days of microbiology. Now, thirty-five years after his death, Haffkine has attracted the attention of many biographers. Two biographies appeared almost simultaneously—one from the U.S.S.R. and the other from the United States. On the hundredth anniversary of the birth of Haffkine, a special postage stamp was issued by the Government of India. This justifies the description aptly chosen by Waksman to end the biography, that Haffkine was "an immortal man of Universe as a whole".

The author has taken elaborate trouble to trace the early life of Haffkine, which was beset with financial difficulties and political as well as religious upheaval against the Jews in Odessa. Perhaps it was then that the spirit of adventure in Haffkine was kindled, as is apparent from the biography.

The leaving of the University of Odessa and his migration to Switzerland and Paris are described as a course of events, which seemed unpurposeful but compelling. It must have been his scientific curiosity, reading and zeal which brought him to the feet of that acknowledged master, Louis Pasteur.

The author has cited with excerpts from "both sides of the story" many comments on the scientific achievements of Haffkine written by his contemporaries. Reading in between the lines, the opposition was mainly motivated for reasons besides those which are normally associated with scientific controversy. His critics never missed the opportunity to attack him right up until his death. Despite all the set-backs that Haffkine encountered in the Malkowal disaster, so well described by Waksman, reason and justice prevailed.

Such a torment to a scientifically inclined missionary in a foreign land did change Haffkine, who returned to India victorious but without his fiery zeal. Not much is known of his later contributions. It was true in Haffkine's life that, if anything is worse than war lost, it is war gained. His later life is described by Waksman as religious. Perhaps Waksman puts his finger on it when he states that he felt his living with Indian people made him change his philosophy of life.

With all this, the author should have paid a tribute to British justice and British recognition of merit despite intrigues that tortured Haffkine. A tribute is also due to Haffkine himself for the metal he was made of to withstand the opposition, insults, injustice and unfair criticism. These need to be inculcated in all scientists and public servants.

The author has taken excerpts from the *British Medical Journal*, the *Lancet* and other medical journals and has made a very correct appraisal of Haffkine's eminence in science. His eminence, however, does not count because of his persecution at any stage of life, though these made Haffkine what he was. He did not seek recognition and he was humane. Persons with such towering personalities, humility and scientific genius need to be highlighted to posterity: Waksman has done a great service to posterity by preparing this biography. No one will be left in doubt after reading this authentic independent adjudgment of Haffkine that he was one of the pioneers in the field of prophylactic bacteriology, to whom the world owes so much.

The book is briefly, but well, illustrated. There appear to be no printing errors. A bibliography of Haffkine and the references cited by Waksman will help medical his-

arians of the future. Science believes either in one world or that it has a world of its own with no barriers. Biography teaches this lesson and here the message is conveyed through Haffkine's life by Waksman's efforts. Haffkine has become immortal in science and his life will continue to inspire microbiologists for a long time.

H. I. JHALA

PLAIN MAN'S GUIDE TO RADIO PROPAGATION

Ionospheric Radio Propagation

By K. Davies. (National Bureau of Standards Monograph 30.) Pp. xiv+470. (Washington: Superintendent of Documents, U.S. Government Printing Office, 1965.) 2.75 dollars.

IONOSPHERIC Radio Propagation is a successor to the National Bureau of Standards Circular 462, published in 1948 under the same title. It is interesting to compare the contents of the two. The new book has more than twice as many pages, but the difference in volume is not great because of the large page size and closely packed layout of the older book.

Not all the new book was written by Dr. Davies, and some sections have been contributed by his colleagues. However, the book is much more of an entity than Circular 462, in which each chapter has separate authorship. The main difference between the books lies in the subjects treated. Some topics such as magneto-ionic theory and an outline of ionospheric physics find an important place in both. The 1948 book fits its title very closely and could be regarded as a handbook for the communication engineer, with substantial chapters devoted to the practical aspects of radio communication. In the 1965 book these topics represent a much smaller proportion of the total. This is largely because they have since been well treated in other publications, to which Dr. Davies refers; but a contributory reason, one suspects, might be that some topics have not progressed sufficiently to warrant extensive coverage. Their place has been taken in the new book by important subjects developed since 1948. These include very high frequency scatter propagation, and low frequency and very low frequency propagation. Another new chapter deals with ionospheric disturbances and their effect on propagation predictions.

With the change of subject-matter has come a change in emphasis. The new book seems to be written not so much for the communications engineer as for a more academically minded readership, the scientific research worker and perhaps the graduate student. So, being personally unfamiliar with some of the topics included, I tried using the book as a tutorial text. In some places the book seemed to fulfil this purpose; in others the exposition did not seem too clear. The book will perhaps be criticized for being too superficial in some places and too detailed in others. In my opinion, books of this type can scarcely hope to escape such criticism, and this one does not seem especially bad in this respect.

The book is provided with 'subject', 'author' and 'place' indexes. The innocent reader might enjoy the index of places; there are naturally experimental stations and scientific institutions (Comfort Cove rubs shoulders with Central Radio Propagation Laboratory), but the entries also include radio stations (GBR, Decca, Loran C); a conference venue (Lindau); and a publishing house (London). The general and the particular are delightfully mixed, as in the consecutive entries, South America, South Ice, South Pole and, again, Scandinavia, Seattle, 75° geographic meridian.

Seriously, this is a useful book. Its clear type, stiff binding and handy page size are a great improvement on the old Circular 462, and at its very modest price it offers excellent value for money.

H. RISHBETH

THE MARINE ATMOSPHERE

Physics of the Marine Atmosphere

By H. U. Roll. (International Geophysics Series, Vol. 7.) Pp. viii+426. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 107s. 6d.

PHYSICS of the Marine Atmosphere is written by Dr. H. U. Roll, the distinguished German meteorologist and oceanographer. As he claims in the preface, this book sets out to describe marine meteorology as an exact physical science, and so great emphasis is placed on the physical approach to problems of the interchange of properties between the ocean and the atmosphere. The book is probably the first to be published that deals with the subject as a pure science and not as an applied science. There are six chapters which are further sub-divided. The first chapter is an introduction while the second chapter deals with meteorological observations and measurements at sea and contains a review of instruments and methods. The third chapter deals with the composition and properties of the marine atmosphere and includes a discussion of the properties of atmospheric nuclei above the oceans, the chemistry of the marine atmosphere with a sub-section on the still rather contentious subject of carbon dioxide interchange, and also an account of atmospheric radioactivity and electricity.

The backbone of the book is, however, contained in Chapters 4 and 5. Chapter 4 deals with aerodynamic considerations of the interchange of energy between the atmosphere and the sea and contains sections on the geometry of the sea surface and also on the wind profile over the ocean. Chapter 5 gives the thermodynamic approach. Some concluding remarks are given in Chapter 6.

As an oceanographer, I was most interested in Chapter 4. This starts with an account of waves and ripples and gives a brief résumé of recent theoretical work on the subject. I found this part slightly disappointing, however, as the author confines himself almost entirely to theoretical work and to discussing wavelets and ripples, and gives very little attention to the large waves ordinarily found on the sea surface and which must affect the marine atmosphere. It is true that theory cannot as yet fully explain the formation or predict the magnitude of ordinary sea waves and recourse has had to be had to various empirical methods which have not hitherto been in agreement with each other. The problem should not be ignored, however, simply because it has not been solved, especially as recently a much greater degree of agreement has been obtained by various workers about the empirical approach. It is now generally agreed, for example, that the significant height of fully developed waves is given by:

$$H \text{ (in ft.)} = 0.018W^2 \text{ (in knots)}$$

where W is the surface wind and full development is reached for fetches less than 400 miles for all wind speeds. This relation should be of interest to both the practical and theoretical marine meteorologist.

The section on the determination of wind profiles over the sea surface is very interesting and it leads on to the evaluation of the wind stress constant over the water surface. There are three traditional methods for determining this parameter. The first obtains it from the wind profile over the first few metres over the surface. The second uses the departure of the mean wind speed from sea-level to the level the geostrophic wind speed is reached from the geostrophic wind speed. The third method is purely oceanographic and involves the measurement of the tilt of the water surface in equilibrium with the wind force. These three methods, however, rarely agree although, to judge from the table shown, there is much better agreement with strong winds. The author criticizes the tilt method generally and in particular a determination in which I had a part, because the effect of the set-up due to wave action is ignored. He suggests that wave set-up

might at least partly explain the apparent increase of stress coefficient with fetch which was found. The effect of wave set-up was certainly not appreciated in 1955 when these results were published, but a recent paper by Longuet-Higgins and Stewart has shown that waves only increase the set-up when their height is limited by breaking, as otherwise the effect is reversed and they reduce the set-up. The recording apparatus in this case was laid in about 2-ft. water depth so the mean wave height should be about 3 ft. for continual breaking, but this value was only very rarely attained during the course of the measurements. The effect of wave set-up is very important nevertheless, and the author rightly points out that tilt experiments should be so designed that this effect is a minimum.

These are all minor points of criticism, and the book is an excellent exposition of the subject and will, I hope, inspire a more widespread study of it. It should certainly be in the library of every oceanographer and every meteorologist.

J. DARBYSHIRE

LIQUID-PHASE OXIDATION OF HYDROCARBONS

The Oxidation of Hydrocarbons in the Liquid Phase

Edited by N. M. Emanuel. Translated from the Russian by K. R. Dobson and B. J. Hazzard. Pp. xv+407. (Oxford, London and New York: Pergamon Press, 1965.) 140s.

THE oxidation of hydrocarbons has been the subject of intense investigation for a long time, and particularly so during the past 20–30 years. Oxidation in general is of paramount importance, not only in chemistry, but also in biology and in other related sciences. The oxidation of hydrocarbons is mainly of interest in chemistry, both because of its academic and industrial aspects. In the organic chemical industry oxidation reactions of hydrocarbons play a very important part and great developments are still occurring in this field.

This book deals with certain aspects of the oxidation of hydrocarbons in the liquid phase with gaseous oxygen as oxidant. Even early workers found that the chemistry of these reactions is complex, and it is not surprising, therefore, that progress has been slow. It was established in the early 'thirties that these oxidations proceed by a chain mechanism and show the complex characteristics of reactions of this type. A first real understanding of the mechanism, although confined to the initial stage of the reaction only, was obtained as a result of the work of Criegee and Hock in Germany and of Farmer and Bolland in Britain. This work revealed the central position of hydroperoxides and hydroperoxy radicals in the reaction scheme and led to a mechanism for the first stages of the oxidation of olefines, paraffins, cycloolefines and alkylaromatics which has been generally accepted.

However, if oxidation is carried on to conversions greater than a few per cent, complications arise which greatly influence the course of the reaction. This characteristic feature of oxidation reactions is very important because the industrial processes operate in this range of conversion which extends from about 2 to 30 per cent.

During the past ten years or so the Russian workers, whose collective effort is represented in the book under review, have been concerned with this problem and have made important and far-reaching advances in the understanding of the reaction mechanism at the later stages of oxidation. One must be grateful to N. M. Emanuel for having assembled, as editor, his own work and that of Knorre, Maizus, Denisov, Bashkurov, to name only a few, in this book, which has now been translated from the Russian by K. R. Dobson and B. J. Hazzard, and edited by J. D. Hopton.

Apart from this group of papers dealing mainly with the mechanism of the oxidation reaction, the book also

contains a collection of papers which are concerned with the technical and more phenomenological, as distinct from the detailed mechanistic, aspects of the liquid-phase oxidation of hydrocarbons.

Discussing first the former group of papers, Emanuel and his colleagues have made good use of the theory of gas-phase oxidation reactions developed by Semenov. Particularly, the concept of the degenerate chain branching reaction has proved very useful in explaining many features of the liquid-phase oxidation at the large extent of reaction. In this case degenerate chain branching is due to the decomposition of the hydroperoxides formed as primary products of the reaction. This is the main factor causing the characteristic self-acceleration of the reaction. In addition, other change in the reaction mechanism occur at this stage. For example, Denisov has shown that the original chain carriers are replaced by others derived from the oxygenated products. The new chain carriers may be less reactive than the original ones and thus slow up chain propagation resulting in a retardation of the overall reaction.

These complex conditions have been analysed in a quantitative manner, which leads to an explanation of many features of the oxidation reaction at higher conversions. Other characteristics such as the influence of inhibitors of various types also agree with the reaction scheme. These are important achievements well brought out in the group of papers on mechanism. The only criticism I have is a certain obscurity and even incompleteness in the definition and explanation of the symbols used. As a result it is sometimes unnecessarily difficult to follow the mathematical derivations.

As for the group of technological papers, they are concerned with a variety of industrial aspects of hydrocarbon oxidation such as the oxidation of paraffins to fatty acids, cyclohexane to cyclohexanone and cyclohexanol, the oxidation of fuels under storage and the inhibition of this oxidation.

None of the work reported in the latter group of papers is radically new; but it is of great value to have collected in one volume this information, which is otherwise scattered throughout the literature and patent specifications. It should be of particular value to anyone who wishes to orient himself in an unfamiliar field.

This book clearly is to be welcomed and recommended to anybody interested in the oxidation of hydrocarbons in the liquid phase.

The translation is good and readable, and the publishers are to be congratulated for having made the book available to the many who cannot read it in the original language.

H. STEINER

STATISTICS FOR NON-MATHEMATICIANS

Statistical Inference

By Prof. Jerome C. R. Li. Vol. 1: Pp. xix+658. Vol. 2: Pp. xiv+575. (Ann Arbor: Edwards Brothers, Inc., 1964.) 10 dollars each volume.

THE first volume of this very large work has the sub-title *A Non-Mathematical Exposition of the Theory of Statistics* and is a revised edition of the author's earlier work *Introduction to Statistical Inference*. The second volume has the sub-title *The Multiple Regression and its Ramifications*, and is a new book. A brief listing of most of the chapter headings will give a fair idea of the contents. Volume 1: descriptive statistics, normal distribution, sample mean, test of hypothesis, χ^2 , t - and F -distributions, difference between sample means, confidence interval, one-way classification, randomized blocks, linear regression, factorial experiment, analysis of covariance, binomial and multi-nomial populations, transformations, distribution-free methods. Volume 2: matrix algebra, multiple regression, curvilinear regression,

fitting constants, factorial experiments, multiple-factor experiments.

Modern statistics is a mathematical discipline and yet its results are required by people with the very minimum of mathematics, and, in many cases, with a hostility toward the subject. It is therefore one of the hardest tasks a statistics teacher has, to explain his subject to many users of it. Prof. Li's way out of this difficulty (in Volume 1 at least) is to introduce the student to the ideas by means of sampling experiments. Thus, a simple finite population is repeatedly sampled and the behaviour of the sample means discussed. A little further on in the exposition a normal population is similarly sampled and the t -, F - and χ^2 -distributions obtained. In this way the student gains familiarity with random variation, can understand how the unusual sometimes happens, and even when, in the more complicated situations, he does not perform the sampling experiments, can appreciate the results in simple terms. A serious disadvantage to this method is that the student does not know which of the conditions of his sampling experiment are essential to the result, and which can be removed. But the author is careful over this point and states the results rather clearly in the form of theorems. With the assumptions on which the results are based stated therein, the student should not fall into the trap that most non-mathematical users of statistics succumb to, and apply the results without criticism in entirely inappropriate situations. The author is similarly very careful over his use of mathematical symbols and introduces them with much explanation.

If the exposition is novel in this respect it is no less novel in its adherence to the normal distribution (or population). Until p. 443 of Volume 1 it is the only population discussed, and no other gets a look-in in the second volume. Even when other distributions (for example, binomial) appear, the methods used involve reduction to normal terms. The extreme example of this is the short (for Prof. Li) chapter of 18 pages on distribution-free methods. He says "the selected [methods] are those which need practically no introduction of new principles". It is not surprising therefore that they "turn out to be the very same methods in disguise".

A second unusual feature is the emphasis placed on multiple regression. This comes relatively early in the exposition and, most remarkably, before the usual constants model for analysis of variance situations. The reason for this is that Prof. Li works through this latter situation in terms of 0, 1, or other appropriate variables and performs a multiple regression with them. Both these novelties have the advantage of giving statistics a unity in that everything stems from the minimum of principles, but I felt that the unity was rather forced.

Without the precision of the mathematical language it is difficult not to make errors. There are quite a few in the 1,233 pages. The most serious is the mis-statement of one of the "only two important theorems given in this text [Volume 2]". This refers to the F -distribution of regression over residual mean-squares, and completely omits to state that it only holds under the null-hypothesis (p. 99). In discussing the limiting form of a histogram (p. 14 of Volume 1) the areas are wrong. The necessity for the two samples to be independent is not mentioned when comparing their variances by the F -statistic (p. 123 of Volume 1), though the point does arise later (p. 137) to be forgotten again on p. 146. No attention is paid to the non-additivity of χ^2 (p. 476). The important point of the transformations being monotone is omitted when discussing the invariance of the median (p. 528).

In addition to errors there are some points which seem unfortunate: the emphasis on significance tests instead of confidence intervals, for example, especially when the former are very firmly of the 'accept-or-reject' type. The unusual notation for regression coefficients (partial and otherwise), which is the opposite of the usual practice, is unnecessary.

These books present an interesting approach to the instruction of non-mathematicians in statistics. If the approach fails, it does so not because the approach is not sound but because it is given in a text which has certain deficiencies, mainly arising out of an emphasis on unity, and is perhaps a little out-of-date. D. V. LINDLEY

INTERNATIONAL NUTRITION

World Review of Nutrition and Dietetics

Vol. 5. Edited by G. H. Bourne. Pp. x+381. (London: Pitman Medical Publishing Co., Ltd., 1965.) 115s.

THE fifth volume of reviews of subjects in the international field of nutrition opens with two essays on nutrition education. The first, by Prof. Beeuwkes of the University of Michigan School of Public Health, gives a good account of the history and the methods of education at all levels in the United States. The second, by Mr. McKenzie and Miss Mumford of Queen Elizabeth College, University of London, presents a critical evaluation of some existing education programmes.

The third paper, from Dr. Todhunter of the University of Alabama, considers some aspects of the history of dietetics and attempts to clarify the differences which may be defined between nutrition and dietetics. It is pertinent to quote the last sentence of the review as a reminder to all who work in the field of nutrition or dietetics. "Food and diet are more than a means of existence, or even of a way to health; they are part of a total way of life and culture of a group and both the nutritionist and dietitian must continue to be cognizant of this fact."

An extensive study of present concepts in diet therapy by Dr. Johnson of the Grace-New Haven Hospital follows Dr. Todhunter's historical review and provides much useful information on normal and modified diets. Adjustments of food intake in quantity and in nutrient content have been seriously investigated in the past forty years, and modern dietary treatment is based on solid scientific investigation rather than the empirical and often fallacious concepts that were accepted in the past.

Some aspects of the metabolism of vitamin A and carotene are reviewed by Dr. Owen of the Hannah Dairy Research Institute, Ayr. Particular attention is directed to the origin and function of liver stores of vitamin A in relation to the composition of blood and milk and the effects of hormones. The functions of retinenes in the vision of various animal phyla are considered. Some recent studies of the relation of vitamin A to enzyme systems concerned with metabolism of sulphate and trace elements are reviewed. Dr. Mahadevan, Dr. Malathi and Dr. Ganguly of the Indian Institute of Science, Bangalore, also review vitamin A in relation to the effect of proteins on absorption of the vitamin. The importance of researches in this field is stressed with reference to the observation that protein malnutrition may precipitate vitamin A deficiency in man.

Dr. Holmes, of the University of Adelaide, makes a useful appraisal of the evidence on which recently recommended protein allowances have been based. Recent recommendations from the United Kingdom, the United States, the Food and Agriculture Organization and Australia are compared with critical reference to discrepancies.

An extensive documented review of bone pathology in experimental malnutrition is given by Mr. Stewart of the Human Nutrition Research Unit, National Institute for Medical Research, London. The final paper of the volume is concerned with the fate of selenium in animals. It comes from Dr. Ganther of the University of Wisconsin.

The nine reviews add up to another valuable collection of information of general interest. A. M. COPPING

CHARACTER RECOGNITION BY HOLOGRAPHY

By PROF. D. GABOR, F.R.S.

Department of Electrical Engineering, Imperial College of Science and Technology, London

WAVE-FRONT reconstruction or holography, on which the first report¹ was published in *Nature* seventeen years ago, had a powerful renaissance in the past years. E. N. Leith and J. Upatnieks², G. W. Stroke³ and others have greatly improved the original method, and showed that it was possible to reconstruct complicated two- and three-dimensional objects, with half-tones, in previously unattainable perfection. The revival of holography owed much of its impulse to the invention of the laser, which made it possible to produce holograms with interferences of the order of 10,000, and thus to make full use of the information capacity of fine-grain photographic plates.

I wish to show that it has now become possible to harness holography for the solution of one of the most urgent problems of computers and other data-processing devices; the recognition of characters with many variants.

Wave-front reconstruction contains a principle which has not yet been fully exploited. Expressed in a general form: two coherent waves are made to fall simultaneously on a photographic plate, one coming from an object *A*, the other from an object *B*. The photograph links these together in such a way that if the hologram is illuminated by *A* alone, *B* will appear too, and vice versa. So far this principle has been applied in the form that *A* was the object of interest and *B* a light source, usually a simple one, and in the reconstruction the hologram was illuminated by *B*. I now propose to turn this around. Let *A* be a character, such as a printed or hand-written letter or numeral, which can be read by human beings but not by a machine, and let *B* be a combination of point-sources, forming a code-word which can be read by a machine. Produce the hologram by combining *A* and *B*. When *A*, or a character sufficiently close to it is presented to the hologram, with the original illumination, the code-word *B* will flash out. This means that the hologram can act as a translator, or coding device.

The interest of this principle is in the enormous recognition capacity which can be stored in a single hologram, and which one might not perhaps suspect at first sight. I wish to show that with *N* characters to be discriminated, each with *M* variants, the product *M.N* can be made of the order of a thousand or even more.

Fig. 1 shows the optics for producing the master hologram, and for using it in the read-out. The recording medium is assumed to be a transparency, such as a microfilm; but reflecting media can also be used. The hologram is built up by repeated exposures in what may be called 'layers'. These are not, of course, physically separated in the emulsion. Each layer corresponds to one of the *N* characters to be discriminated, with all its *M* variants, and is marked with one code-word. The layer contains the part-holograms, to be called 'engrams' of the variants side by side, with little overlap. Each engram is produced with one direction of illumination, and as the photographic plate is arranged in the rear focal plane of a lens viewing the character, it is a 'Fourier-hologram'. This has the advantage that the hologram is translation-invariant, that is to say, independent of the position of the character so long as this appears alone in the window. An engram need not occupy much more area in a photographic plate than would be needed for a good record of the corresponding character, but as a cautious example we will assume 120 engrams, each with a diameter of about 5 mm, on a photographic plate of 50 mm × 50 mm. This is sufficient to record without overlap 30 variants, each in four or six 'identical' engrams. Fig. 1 shows how this is achieved.

The light of a laser issues from a point *L*, and a beam splitter consisting of a spherical mirror and a semi-reflecting mirror produces of this two images *L'* and *L''*. The first of these serves the illuminator; the second, in the centre hole of the illuminator plate, serves the code plate. The illuminator plate, backed by a field lens, consists of a plastic plate embossed with, say, 120 lenticules, and is black outside the lenticules. These produce 120 point sources which illuminate the window containing the character through a lens 1, which removes the illuminator points into star space. The point sources correspond one-by-one to the engrams. There is a certain advantage in randomizing them slightly. Four identical engrams are taken at a time of any one variant. These are spaced out, as far as possible, to increase the resolving power of the hologram. They are selected with a mask, and a different mask with four holes is used for every variant.

Fig. 1. Apparatus for producing a coding hologram and using it for the read-out

The point source L'' in the centre of the illuminator plate illuminates the code-plate, through the same lens 1, which serves in this area as a field lens. The code-plate, like the illuminator, is an embossed plastic plate, which contains the code-word in the form of groups of luminous points, arranged in one or several arrays. It is advantageous to use self-checking codes, in which every word has the same number of code-points. In the example here are six positions, of which two remain dark and four light up. This code has $6.5/1.2 = 15$ words. Two more positions have been added. These do not contribute to the discrimination of characters, but improve the signal-to-noise ratio, as eight points have to light up for every valid character.

In the making of the master hologram all engrams in one layer are marked, that is to say, exposed simultaneously, with one distinctive code-word, which is selected by a mask. But as each code-word illuminates the whole area of the hologram, a further mask must be used near the plane of the photographic plate, which cuts out the light except in the area of the engrams which are made at any one time. This makes it possible to observe the rule of optimum illumination, which postulates about equal light sums on any engram from the character and from its code-word.

Black-on-white letters are less suitable for discrimination than their negatives, because they have too much in common; all their white area. But this disadvantage can be eliminated by a further mask, in the plane of the hologram, which cuts out all undiffracted light. By Babinet's principle this turns a character into its negative. Such a mask can be easily made by exposing a photographic plate through a clear window simultaneously to all illuminator points.

After $M.N$ successive exposures of the photographic plate, which add up to a convenient medium density, the master hologram is made by processing and printing it, preferably with an overall gamma of 2, and the print is put back in the original position. In the reading all the point-sources of the illuminator are used, while the whole code-plate is covered up. A lens 3 is used for observation, which produces a real image of the code-plate. If now the recording medium is dragged across the window, whenever a character or a variant appears in it, its code-word will flash up. It is advantageous to arrange in the image plane a mask, which is a replica of the code-plate, with very fine holes, so as to exclude all but the signalling light. This mask, too, can be made photographically.

A method of reading the code-words is to sum up all the light which appears in one zone, corresponding to one position in the code, and guide it to a separate photo-electric detector. Each detector is fitted with a level discriminator, so as to reject spurious signals below a certain level. This method is simple; but it has only

moderate discriminating power, because if the characters are not clearly distinct, some light might show up in the same zone in the code-words of other characters. One can reduce this by making the code-words of characters which are not clearly distinct as different as possible. But the maximum of discrimination is achieved by a somewhat more complicated apparatus. In this the image of the code-plate is projected on the screen of an image camera. The code-words flash up at intervals corresponding to the time allotted to each letter, during 10–30 per cent of this period. In the time between flashes all code positions are scanned word by word, and points above a certain level of intensity are transferred to a memory organ, such as a core store. But unless the full number of points appear in a word, the record is erased. If the full number is counted, the code-word is transferred to the computer.

The great discriminating power of the holographic method stems from its high angular resolution. Assume, for example, $N = 35$, $M = 30$, $M.N = 1050$. The group of four engrams corresponding to the character presented to the reader receives $1/30$ of the light, and can diffract about $1/35$ of it, altogether about 10^{-3} of the total. (Not counting, of course, in black-on-white records, the undiffracted light which goes into the zero order.) Of the diffracted light, under the proper conditions, that is to say, when the engrams were taken with about equal light sums from the letter and from the code-word, one-quarter will go into the reconstruction of the code-word. One half appears in the object, another quarter goes into the 'twin' image of the code-word, which, however, is washed out by intermodulation with the character, and is useless for recognition. But the useful quarter is concentrated in extremely small solid angles. For example, if four or six identical engrams are spaced out by about 25 mm, the solid angle in which the major part of the light corresponding to a code-point is concentrated will be of the order 10^{-3} . Let the light of, say, 10^{-4} of the total be distributed among ten code-points, this means that 10^{-5} of the light appears in one code-point, in a solid angle which is perhaps 10^{-3} of the solid angle covered by the whole code; a concentration of the order ten. Moreover, this estimate is somewhat pessimistic, because it takes no account of the confirmation of the character by the engrams of slightly different variants in the same layer.

In conclusion, there is good reason to believe that a single hologram may discriminate between all the numerals and the letters of the alphabet, each with 30 variants.

POLONIUM-210 IN MAN

By Dr. C. R. HILL

Physics Department, Institute of Cancer Research, Belmont, Surrey

IT is well known that the atmosphere contains appreciable quantities of radon as a result of emanation from the materials of the Earth's crust. Until recently, however, little interest has been taken in the fate of the long-lived radionuclides produced in the atmosphere by radon decay. Radium *D* (lead-210) has a half-life of twenty-two years, much longer than the twenty–thirty day mean residence time for aerosols in the troposphere, and it is therefore returned to the surface of the Earth as a natural component of fall-out. During residence in the atmosphere, sufficient time elapses for the growth of most of

the equilibrium amount of the five-day β -emitter radium *E* (bismuth-210) and some of the 138-day α -emitter radium *F* (polonium-210), and these therefore also take part in the fall-out process.

In addition to this natural process of production, polonium-210 may be released into the atmosphere by a number of artificial means. Considerable quantities are thought to have been released by the Windscale accident in 1957 (ref. 1). It is being used as a source of thermal power in Earth satellites and there has recently been interest in the possibility that a certain amount may have been

produced by activation of stable lead or bismuth in nuclear weapon explosions. Except, possibly, in the stratosphere the natural source of the nuclide is predominant at the present time, but this may not always remain the case.

Burton and Stewart, in 1956, measured the concentration of radium *D*, *E* and *F* in ground-level air and in rain-water at Harwell³ and their figures show an annual deposition rate for radium *D* of about 1.7 mc./km² (ref. 2), which is nearly half the corresponding mean rate for strontium-90 recorded at the same site during the past five years³. The concentration of radium *D* in ground-level air appears to be dependent on latitude, being highest in temperate latitudes and also being generally higher in the northern than in the southern hemisphere⁴, possibly as a result of the difference in exposed land masses.

Dispersion as an atmospheric aerosol is well known to be an effective means by which many trace materials may gain entry to the biosphere. Lead, bismuth and polonium may all be absorbed by human beings as a result of inhalation and also to an appreciable extent by uptake through the gut⁵: it is therefore of interest to know to what extent human beings may be exposed to these nuclides in the environment and whether, in fact, they are normally present in human tissues.

From knowledge of the energy and linear energy transfer of the radiation emitted by the three nuclides radium *D*, *E* and *F*, it appears that the respective biologically effective doses produced per disintegration will be in the approximate ratios 1:10:1,000 (assuming an RBE of 10 for α -particles). It is radium *F* (polonium-210) that is of primary interest, therefore, in the present context, although it must be borne in mind that its actual presence and pattern of distribution in the human body may be determined very largely by the behaviour of one or more of its radioactive precursors.

Human and animal foodstuffs. Polonium-210 has been observed to occur on exposed foliage, and particularly on grass, in amounts that are directly related to local rainfall⁶. In high rainfall districts in England and Wales concentrations above 10,000 pc./kg of dry grass are not uncommon, with the curious consequence that a load of hay can become legally classifiable as a 'radioactive substance' purely on account of its natural radioactivity. Concentrations of the order of 5,000 pc./kg have also been found to be common in slow-growing plants such as lichens, both in the United Kingdom and also in Lapland and the Canadian Arctic, where they form an important part of the winter diet of reindeer and caribou.

Grazing animals are found to take up polonium-210 in appreciable amounts, and concentrations greater than 1,000 pc./kg have been found in some animal tissues both

in the Arctic and in high rainfall areas of the United Kingdom. Biological concentration of polonium-210 also occurs in some marine organisms and in particular in some varieties of plankton⁷, certain shellfish and crab. Evidently, therefore, there is a considerable variety of ways in which the nuclide may find its way into human and animal foodstuffs, and the amounts that we have measured in a number of these⁸, together with observed values of the lead-210:polonium-210 activity ratio in certain cases, are shown in Table 1.

The data of Table 1 are somewhat fragmentary and are characterized by wide variations in the concentrations of the nuclides, but it may be concluded that the daily intake of both polonium-210 and lead-210 in the food comprising an average mixed western diet will probably be in the range 1–10 pc. This estimate is supported by measurements we have made of the daily faecal excretion of lead-210 by a thirty-year-old male subject consuming an ordinary 'English' diet. For six separate samples collected at intervals over five months the values were between 1.7 and 6.4 with an average of 3.2 pc./day. From similar measurements in the United States, Holtzman has obtained a value of 1.8 pc./day⁹.

Evidently a considerably higher figure might apply, for example, to a connoisseur of sea food, while an Eskimo on a high meat diet based on winter-killed reindeer might ingest of the order of 100 pc./day of each nuclide. It is to be noted that the polonium-210 and lead-210 contents of drinking-waters (other than untreated rain-water) are only of the order 0.01 and 0.05 pc./l. respectively⁹ and so would probably be insignificant in comparison with food as a source of ingestion of the nuclides.

Tobacco and cigarette smoke. It has been pointed out by Radford and Hunt that appreciable concentrations of polonium-210 occur in tobacco and that, as might be expected from the known volatility of polonium, a considerable fraction of the activity in the tobacco may be transferred to the inhaled smoke¹⁰.

I have measured polonium-210 concentrations in a number of cigarette tobaccos of different origin, with the results shown in Table 2. These figures do not indicate any striking differences as between the different major tobacco-producing areas and, in particular, do not support the suggestion recently made by Marsden¹¹, based apparently on total α -activity measurements only, that differences in the polonium-210 content of tobaccos might be related to geographical variations in the incidence of lung cancer.

We have also investigated the fate of the polonium-210 which is present in a cigarette when it is smoked in a standard smoking procedure†. Using a popular brand of cigarette which was found to contain 0.49 ± 0.07 pc. polonium-210 per cigarette, the fate of the original activity in three experiments was as shown in Table 3, where the previous results of Radford and Hunt are summarized for comparison. It will be seen that the main conclusion from the earlier work, that an appreciable fraction of the polonium appears in the main-stream

* Apart from a limited number of α -spectroscopy measurements, the polonium-210 determinations reported in this article have been carried out by the method described by Black (ref. 27), Osborne (ref. 12) and others. Samples are wet ashed using nitric and perchloric acids and polonium is then deposited electrochemically on to silver from a solution in 0.5 N hydrochloric acid, and afterwards α -counted. Yield is checked using duplicate samples spiked with a standard ²¹⁰Pb-²¹⁰Po solution and lead-210 can be estimated by replating polonium-210 from the solution after an interval of several months.

† Smoking was carried out under the following conditions, using a bellows type smoking machine: initial cigarette length 70 mm, weight 1.09 g; butt length 23 mm; puff volume 35 ml., duration 2.0 sec, repeated once a minute to total 10 puffs per cigarette; horizontal smoking position. In experiment No. 3, filter tips were fitted to the cigarette, using adhesive tape. Main-stream smoke (that is, the fraction normally drawn into the mouth) was drawn directly into the collecting device, which was either a Cambridge filter (expts. Nos. 2 and 3) or two wash bottles containing 5 per cent hydrochloric acid in ethanol and immersed in solid carbon dioxide (expt. No. 1). Side-stream smoke was led through a collecting chimney and collected either in two similar wash bottles in series followed by two Cambridge filters in parallel (expt. No. 1) or in the two filters only (expts. Nos. 2 and 3). Following collection, smoke was recovered from the filters by gently flowing hydrochloric acid-ethanol mixture in the reverse direction through the filters, still in their holders. Polonium-210 estimation was carried out as described in the previous footnote.

smoke, is confirmed, although the actual fractions found in the present experiments are somewhat lower, possibly as a result of differences in smoking conditions.

In a separate experiment, main-stream smoke from cigarettes from the same batch was weighed after collection on Cambridge filters and found, in two separate measurements, to amount to 0.032 g per cigarette as collected or 0.021 g after drying at 100° C. Taking the polonium-210 content of main-stream smoke as being about 0.05 pc. per cigarette (from the foregoing measurements) it is evident that the specific polonium-210 α -radioactivity in the condensed smoke is of the order of 2 pc./g. The radiation dose rate at the surface of a thick (that is, > 100 μ) slab of such material would be 0.1 rad (or 1 rem) per year and less for thinner slabs. This is of interest in considering the possible occurrence of high local dose rates in the human lung as a result of accumulation of smoke particles, since the foregoing dose rate is in marked contrast with the values of from several hundred to more than 1,000 rems in twenty-five years suggested by Radford and Hunt¹⁰. For such high dose rates to occur it would seem to be necessary to postulate a mechanism for selective clearance from the lung of the bulk constituents of the condensed smoke relative to that of polonium-210. Such a mechanism would not only have to show a high degree of selectivity but also, on the evidence given later for retention time in the lung for the polonium-210, would need to operate rather rapidly.

Normal human tissues. A number of measurements have been reported of the concentrations of polonium-210 and lead-210 in normal human tissues, although, apart from those by Osborne¹² and Stahlhofen¹³, most have been concerned only with bone and teeth^{8,14,15}. In view of the

results presented here, I have made two further sets of measurements on human tissues. In the first place I have examined the polonium-210 levels (equivalent to lead-210, as the samples were several years old at the time of measurement) in bones of ten different Canadian Eskimos. Secondly, I have made comparative measurements of polonium-210 on soft tissues of two groups of individuals known to be non-smokers and regular cigarette smokers respectively, all of whom died sufficiently suddenly that their smoking and other habits would not have been upset seriously for more than a few hours before death. Measurements were made without subdivision of the tissues except in the case of the right lung, where the bronchial tree and samples of peripheral alveolar tissue were dissected out and measured separately. In three cases the secondary bronchial bifurcations were dissected out (to include about 0.5 cm of bronchus above and below the bifurcation) and measured separately. The results of measurements on the Eskimos and on the effect of smoking are presented in Tables 4 and 5 respectively.

The measurements on the Eskimos can be compared with values found by other investigators for bone of 'normal' European and North American subjects (shown in the same Table). From this it will be seen that the Eskimo values range from 'normal' upwards by a factor of twenty or more, and it is interesting that the high values occur in subjects who had been permanently resident in the Arctic while several of the others had been living in southern Canada for some time prior to removal of the bone (either at autopsy or in the course of thoracoplasty). The high values found here seem to be consistent with my observations of high levels in reindeer meat and the known high meat diet of Eskimos.

(Note added in proof. Recent measurements on fresh placental tissue samples derived from nine northern Canadian residents whose diet included reindeer or caribou meat have shown polonium-210 concentrations

twelve times greater, on average, than those found in nine other subjects from the same area.)

From the measurements on smokers and non-smokers (Table 5) the following points emerge:

(1) In both smokers and non-smokers the ratio between gross specific polonium-210 activity in the bronchial tree and that in alveolar tissue is close to unity for any individual.

(2) In liver and kidney the levels of polonium-210 in smokers are little, if at all, greater than those in non-smokers, whereas in lung tissue a difference with a factor of between 2 and 3 seems to occur. This is perhaps best seen in comparison of the activity ratio 'lung/liver' for the two groups. The corresponding ratio 'kidney/liver' may here be regarded as a control parameter indicating variations occurring between two tissues neither of which is directly concerned in the exposure mechanism of interest (inhalation).

(3) In my samples the polonium-210 content of the average smoker's lung exceeds that of the average non-smoker by 5.4 pc. (assuming 1 kg for the total weight of the lungs), which is the approximate content of the nuclide in the main-stream smoke of a hundred cigarettes. Assuming a consumption of twenty cigarettes per day and retention by the lung of half the main-stream smoke, these results suggest a retention time for the polonium-210 in the lung of the order of ten days.

(4) For the three cases of smokers where bronchial bifurcations were dissected out and measured separately, the polonium-210 in each sample (of weight between 5 and 15 g and each consisting of several bifurcations) did not in any case exceed the amount to be expected, from the average value measured for the whole bronchial tree, by more than 0.05 pc.

In view of the possibility suggested by Radford¹⁰ that even such a small quantity of activity might lead to high dose rates if it were concentrated into a small area, I have examined autoradiographically some vacuum-dried samples of epithelium taken from bronchial bifurcations in smokers' lungs. In the specimens examined so far I have not found statistically significant concentrations of α -activity greater than 0.01 pc./cm², and an appreciable part even of this activity is probably attributable to background from the glass plates used in the initial experiments.

My failure to find appreciable excess polonium-210 activity in bronchial bifurcations of cigarette smokers, either when measured as gross tissue concentrations or when examined autoradiographically as surface activity, is in contrast with Radford's observation of hot spot activity¹⁰ and also with his later observations of polonium-210 activities up to 1.25 pc./g in bronchial epithelium¹⁶.

Subjects with high skeletal burdens of radium-226. The decay of radium-226, present in the human skeleton as a result of either natural or abnormal exposure, leads eventually to the formation within the body of a certain amount of lead-210 and its descendants. It will be shown later than in the normal subject this source is of little importance, but in subjects with high radium burdens it can constitute the main source of these nuclides and is of interest therefore as providing an opportunity for an investigation of the effect of differences in the route of their administration to the human body.

I have recently had occasion to examine *post mortem* a subject who had been employed as a radium-dial painter until six weeks before her death, which resulted from acute myeloid leukaemia. Her body-burden of radium-226 proved to be 0.02 μ c.; well below the maximum permissible level, but about one thousand times above normal. The levels of polonium-210 and lead-210 measured in various organs at the time of death are shown in Table 6, both as absolute amounts and as ratios to the corresponding average levels that we have measured in normal individuals. Several interesting points emerge from these figures:

(1) In bone and liver the presence of polonium-210 appears to be due to the quantitative retention of the products of decay of lead-210 in the tissue, since the two nuclides occur in equilibrium. In kidney and ovaries, however, the polonium-210 is significantly in excess of equilibrium and is presumably present largely as a result of active uptake of polonium from the blood. The discrimination between the renal cortex and medulla is in agreement with animal data and with a single previously published case of a human subject¹⁷.

(2) The exposed/normal ratio for polonium-210 in a tissue is much higher for bone than for most soft tissues. This presumably reflects the known fact that an appreciable fraction of the radon produced in bone by decay of radium-226 does not escape but decays there with the eventual deposition of lead-210 and polonium-210. (The high absolute and relative levels of polonium-210 in hair may be due to superficial contamination by radon decay-products in the atmosphere of the luminizing factory.)

(3) The actual distribution of polonium-210 among the soft tissues does not seem to be strongly dependent on the origin of the polonium. It is of particular interest that this observation applies also to the lung: this could be a fortuitous result of the inhalation of high concentrations of radon and daughters, but otherwise it suggests that much of the normal polonium-210 content of the lung originates internally rather than as atmospheric material that has not been cleared physiologically.

(4) In relation to the radium-226 content of the skeleton, the ²¹⁰Pb-²¹⁰Po levels in the soft tissues of the exposed subject are seen to be considerably less, by a factor of about 70, than those in normal individuals. This is in agreement with Holtzman's prediction⁸ that the normal individual acquires only a very small fraction of his polonium-210 burden (at least in soft tissues) as a result of decay of skeletal radium-226.

Measurements have also been made of polonium-210 in the tissues of a number of subjects having radium-226 burdens that had been acquired some twenty-forty years before their death. The results, which are given in Table 7, show a level of polonium-210 in soft tissue, for a given radium-226 burden, that is considerably less than that in the more recently exposed case. This situation is consistent with the older radium deposits being less subject to loss of radon to the blood, but it could also be explained on the basis of high inhalation of radon and daughters by the more recently exposed subject.

If the commonly used value of 0.67 is assumed for the fraction of radon-222 produced in bone that escapes to the blood, the data of Table 7 may be used to calculate the rate of uptake of radon-222 into the blood that would by itself maintain the normal concentration (10 pc./kg) of polonium-210 in the liver. A value of approximately 0.5 pc./min is found in this way.

Table 6. POLONIUM-210 AND LEAD-210 LEVELS IN TISSUES OF A RADIUM-DIAL PAINTER

Tissue	²¹⁰ Po activity (pc/kg)	²¹⁰ Pb : ²¹⁰ Po activity ratio	²¹⁰ Po ratio exposed: normal ¹²
Liver	190	1.0	19
Lung	50	—	15
Kidney cortex	360	0.13	40
Kidney medulla	200	0.10	40
Spleen	34	2.5	11
Ovaries	60	0.25	9
Thyroid	11	—	—
Pancreas	8	—	6
Adrenals	70	—	—
Hair	25,000	1.0	280
Bone	1,500	1.0	88
Bone— ²²⁶ Ra	4,000	—	1,000 (²²⁶ Ra)

Table 7. RADIUM-226 IN BONE AND POLONIUM-210 IN LIVER FOR INDIVIDUALS WITH LONG-ESTABLISHED RADIUM BURDENS

Approx age of ²²⁶ Ra burden (years)	²²⁶ Ra in bone at death (pc/kg wet)	²¹⁰ Po in liver at death (pc/kg wet)	Ratio bone ²²⁶ Ra/liver ²¹⁰ Po
20	9,000,000	11,000	800
40	2,300,000	2,000	1,100
35	2,000,000	4,500	450
30	80,000	70 (normal)	(1,000)
20	40,000	110 (normal)	(400)
40	30,000	80 (normal)	(800)

Isolated proteins. One of the biological properties of polonium that is often overlooked, although it has been known for some forty years¹⁸, is that it is a 'seeker' of soft tissues rather than bone, and it is in fact unique in this way among the α -emitting heavy elements. (The common occurrence of polonium-210 in bone is almost certainly not a result of its own chemical nature but rather of its descent from the bone seeker lead-210.) The reason for this behaviour is not fully understood, although it is known that polonium may be associated with protein, particularly in the blood^{19,20}.

In this connexion it seemed of interest to determine whether the polonium-210 that has been shown to occur in grazing animals may be present in nominally pure crystalline proteins extracted from their tissues. The results of several such measurements on commercially prepared samples are shown in Table 8 together, for one of the insulin samples, with corresponding measurements both on the pancreas from which the sample was derived and on a multiply recrystallized fraction of the commercial grade of protein.

Table 8. POLONIUM-210 CONTENTS OF SOME PURE PROTEINS

Protein	Supplier	²¹⁰ Po activity (pc/kg)
Albumin (crystalline bovine)	B.D.H.	23
Haemoglobin	B.D.H.	98
Gelatine (powder)	B.D.H.	40
Fibrinogen (bovine)	B.D.H.	120
Insulin (crystalline bovine)	B.D.H.	610
Insulin (crystalline bovine)	Boots	1,870
Insulin (crystalline bovine)	Burroughs Wellcome	660
Insulin (crystalline bovine) (multiply recrystallized)	Burroughs Wellcome	370
Raw bovine pancreas (dried)	Burroughs Wellcome	25

The difference in activities between the insulins and the other bovine proteins might simply reflect a difference in origin (the three commercial insulins, although from different manufacturers, were all derived from a common source of supply of pancreas), but it is of interest that, of the various proteins examined, insulin has much the highest content of —SH groups. The reduction in specific activity on multiple recrystallization appears to rule out a very close association between the polonium and the protein, but the possibility is nevertheless suggested that some association, in which —SH groups are involved, may exist. Such a situation would evidently have important implications for the microdosimetry of the polonium isotopes.

Discussion

The selection of data presented in this article has been dictated to a considerable extent by the availability of post-mortem and other specimens and is therefore far from comprehensive. Nevertheless, from these results and others previously reported in the literature, at least the outlines of a consistent picture can be obtained of the part played by the sub-series radium D—E—F in man's radioactive environment.

The correspondence, both for grazing animals and for man, between the levels of polonium-210 in the food of a community and in the tissues of its members clearly indicates that ingestion in food is an important route for acquisition of body-burdens of the nuclide. The conclusion that this is normally the principal source of such body-burdens seems to follow from Holtzman's analysis of other possibilities⁹, including decay of skeletal radium-226 and inhalation of radon-222, radium A, B and C and radium D, E and F, in which he showed that only the last-mentioned of these is of comparable importance with food, and that only if one assumes an atmospheric concentration of the nuclides several times higher than has been measured by most observers²¹.

The variations, by an order of magnitude or more, between polonium-210 body-burdens in 'normal' United Kingdom and United States residents and in some Canadian Eskimos, are probably due to the latter having a high dietary content of meat derived from animals

grazing on poor, slowly growing pasture. Apart from in the Arctic, such conditions might also be expected among the herdsman populations of arid regions such as those in Arabia and East Africa, and it is of interest here that we have found high levels of polonium-210 in camels.

Cigarette smoking does not seem to lead to abnormal levels of polonium-210 in tissues other than lung, and the levels here, examined either as gross tissue concentrations or, so far as I have been able to discover, as localized concentrations, are not such as would lead to abnormally high radiation dose rates. However, the possibility of being able to observe localized concentrations of smoke particles in the bronchial epithelium by virtue of their association with a radionuclide is of considerable interest, regardless of considerations of radiation dose to the tissue, and would justify further experimental effort in that direction.

The question of the part played by physiological uptake of lead-210 in producing tissue concentrations of polonium-210 is still not completely settled^{21,22}. Evidence from work with experimental animals, as summarized by the International Commission on Radiological Protection⁵, indicates that the steady condition reached following prolonged chronic ingestion of an equilibrium mixture of lead-210, bismuth-210 and polonium-210 would be one in which lead-210 was considerably in excess of polonium-210; the predicted ²¹⁰Pb : ²¹⁰Po ratios for bone, liver and kidney being 400, 32 and 25, respectively. Values for this ratio between these figures and unity would still be consistent with the data from the International Commission on Radiological Protection if a fraction of the decay products of lead-210 was retained in the tissue where it had been formed, whereas values less than unity could only be explained by an active uptake of polonium-210 into the tissues (or, possibly, by redistribution of polonium-210 between different tissues²²). In fact, I have repeatedly found values for this ratio considerably less than unity in a number of soft tissues and consistently close to unity for bone. It appears, therefore, that, under the conditions we are studying, there may be a true uptake of polonium-210 into certain tissues independently of lead-210, while in bone the initial uptake is of lead-210 and this is followed by quantitative retention of decay products.

Although this article is primarily concerned with polonium-210 it is of interest that at least four other isotopes of polonium, all α -emitters, are normally present in the human body: polonium-218 (radium A), polonium-216 (thorium A), polonium-214 (radium C') and polonium-212 (thorium C'). Owing to their short half-lives, direct measurements of the tissue levels and distribution of these isotopes have not hitherto been possible, but experimental data obtained with rats²³ indicate that a dose rate to the kidney, due to polonium-218 and polonium-214, of the order of 1 mrad/year may result from continuous inhalation of radon at a concentration of 10^{-12} c./l. On the basis of the behaviour of polonium-210 the corresponding dose rate to the gonads may be expected to be of a similar order of magnitude.

Conclusion

The object of the work described in this article is to define the part played by polonium-210 in contributing to the biologically effective radiation dose received by man in a variety of environments. In the foregoing I have reported the gross concentrations of the nuclide that are found in human tissues, together with some of their variations with environmental conditions, and I have discussed the origin of the material and some information relating to its physiological and biochemical behaviour which suggests that its distribution within a tissue may be rather non-uniform. One major area of ignorance with which we are still faced, however, is in the basis for a comparison of the physical dose rates of high linear energy transfer radiation that we have measured with other,

predominantly low linear energy transfer, sources of background radiation; in other words, the problem of relative biological effectiveness at very low dose rates. In the absence of better evidence we may simply assume a relative biological effectiveness of 10 for the polonium-210 α -particle, in which case, by a convenient arithmetical accident, our tissue concentrations expressed as pc/kg become equivalent to mrem/year. This is almost certainly a very poor approximation to whatever the true position may be, and it should be pointed out that some recent reports²⁴⁻²⁶ have suggested that the relative biological effectiveness for high linear energy transfer radiation may become very large at low dose rates, tending towards values of 30 or more for the conditions of background radiation. On this basis polonium-210 would evidently constitute a major fraction of background dose to man, the total of which is generally considered to be of the order of 100 mrem/year.

I thank Dr. C. F. J. Baron, Dr. D. Haler, Dr. L. A. Barrer and Dr. F. D. Sowby for arranging the supply of post-mortem material; Prof. K. Liden, Dr. J. K. Miettinen, Dr. O. Paakola and Dr. P. M. Bird for the Arctic specimens; Prof. J. E. Roberts for the camel bones; Dr. I. W. Hughes and the British American Tobacco Co. for help in the experiments on cigarette smoking and tobaccos; and Dr. G. A. Stewart, of Messrs. Burroughs Wellcome and Co., for assistance with the measurements on insulins. I am indebted to several of my colleagues for their helpful advice, and to Mr. Howard Dawson for

carrying out most of the measurements. Finally, I thank Prof. W. V. Mayneord for his support and advice.

PATTERN MEASUREMENT

By DR. A. WARD and G. W. McMASTER

Radiation Laboratory, University of Strathclyde

PATTERN measurement is a rapidly growing development which is likely to affect a number of very different fields of study to a much greater extent than has previously been the case. The term is used here to describe any technique in which an instrument (usually of an electronic and optical nature) is used to scan an image or a permanent photographic record of an image, store the information obtained from the scan and finally analyse this information in terms of a series of parameters the quantitative values of which describe the features of the image which are essential, or at least of interest.

Clearly such instruments merely carry out essentially the same function as the combination of the human eye and part of the human brain. Indeed, those engaged in the field of pattern measurement develop a very healthy respect for the flexibility, speed and selectiveness of the human eye and brain in recognizing patterns. Unfortunately, as we all know, the human eye and brain are subject to fatigue; the brain is easily distracted and finds it difficult to remember with complete clarity the details in different parts of the same photograph and in comparing a series of similar photographs.

Bearing in mind the enormous capacity of a photograph to record permanently and conveniently the essential data in an image, it is understandable that most instruments in pattern measurement are designed to scan photographs rather than the original image.

Progress at Strathclyde

Nearly three years ago research and development were begun here to produce a series of instruments for pattern measurement. After a number of abortive starts using electro-mechanical devices of a fairly elaborate nature, the first of these instruments has been completed.

The problem in all instruments of this type, or at least the main problem, is to build into the instrument a very

high degree of stability—short-term stability over periods less than a second and also long-term stability over periods of the order of days, weeks or even months. Unless such stability is present the advantages of the instrument over the human eye and brain are largely lost. There is simply no room for erratic unknown errors in the three processes of scanning, storage and analysis.

Other factors involved include the total number of points into which the photograph can be divided, the geometrical shape of the scan, the range of grain densities that may be encountered, the speed of the scan, the speed, capacity and permanency of storage of information obtained from the scan, the speed of extraction of this information and the flexibility and speed of its analysis. This does not exhaust all the practical factors which are encountered; for example, it is quite important to have visual monitors at different parts of the system, not only to check for satisfactory operation but also to permit satisfactory adjustment of the system to deal with particular types of images. To satisfy the demands of stability, speed and flexibility we have found it necessary to develop purely electronic/optical systems.

The particular instrument described here (Mark 1) is made up of three units which carry out the functions of scanning, storage and analysis respectively. The scanning unit, which will be described in a little more detail later, is an original instrument designed by ourselves in collaboration with General Electric Co., Ltd., who built it for us using modern, fully transistorized circuits. The storage unit is a Laben 512 channel analyser used in its multi-scaler mode of operation, and we exploit three of its facilities for recording the data stored in its magnetic memory unit. These three facilities are a paper-tape puncher, an electric typewriter and a 'Polaroid' camera, which photographs a convenient display of the stored data. The analysis unit is a Ferranti *Sirius* computer.

Scanning Unit

Returning to the scanning unit, this is essentially a flying-spot scanner in which a raster of successive spots of the face of a cathode-ray tube is focused on a transparency (the photograph being examined) in the form of a 35-mm slide. Each spot had a duration of 1/10 of a second, and a measuring photo-multiplier behind the transparency provides a current which is proportional to the amount of light passing through the particular point on the transparency. Circuitry in the instrument converts this analogue current into a digital output which can vary between 0 and 128 depending on the grain density at the point being examined. The darker the film at a point the smaller is the integer which represents the measure of the grain density at this point. The instrument therefore accommodates 128 shades of grey and facilities are provided for varying over wide limits the range of grain densities corresponding to these 128 shades. The lower limit of grain density corresponding to 128 can be varied independently. The raster of points on the face of the cathode-ray tube can have from 4 to 512 points on each line and from 4 to 256 lines in each complete scan. The photograph being examined can therefore be divided into a total number of points varying from 16 to rather more than 125,000. The size of the raster can be varied electronically, thus providing a convenient method of continuously variable magnification in the scanning procedure. The area being scanned can be varied over a factor of 256. For convenience in setting up operations, prior to the actual scanning procedure, a display cathode-ray tube is built into the instrument which provides a reproduction of the selected area of the photograph. This reproduction looks very like the picture obtained on a television monitor. A line grid drawn on the face on this display tube makes it possible to correlate what is seen visually on the display tube, when the instrument is used in the viewing mode of operation, with the output on, say, the paper-tape puncher or visual display of the results of a scan as stored by the Laben 512 channel analyser. As it is possible to move the raster independently in the vertical or horizontal directions, a particular part of the display seen in the viewing mode of operation can be selected for scanning. Much more detailed information on this instrument will be given elsewhere, as it embodies a number of circuits entirely concerned with the problem of stability. However, it may be worth mentioning here that the instrument is driven by a master oscillator in both the high-speed viewing mode of operation and in the slow-speed scan, and a second photo-multiplier is used which monitors continuously the brightness of the spot of light on the cathode-ray tube (which provides the raster) and through feed-back circuits ensures that the amount of light in the spot focused on the transparency remains very constant.

In using the mark I model for pattern measurement a total of thirty 35-mm slides can be loaded into the scanning unit and examined separately one after another. Having viewed a selected slide by operating the scanner in the viewing mode of operation, it is then scanned in a series of 512 points. The 512 integers, varying between 0 and 128, corresponding to the digital output of the scanning instrument, are stored in the magnetic memory unit of the Laben 512 channel analyser. After visual inspection of these 512 numbers of the display tube of the Laben, they are printed-out on the paper-tape puncher. These operations are repeated until the whole of the selected area on one 35-mm slide has been scanned, and stored permanently in the form of the paper-tape print-out. This entire procedure can then be repeated for successive 35-mm slides, the paper tapes being inserted into the Ferranti *Sirius* computer which we programme to analyse the data.

Applications

Clearly this technique can be used to measure patterns in a series of photographs, or even just one photograph,

in a wide variety of fields ranging from studies of chromosomes, a comparison of cancer and normal cells (see pp. 485 and 486 of this issue of *Nature*) to more detailed examination and classification of astronomical objects such as galaxies, Sun spots, the surface of the Moon and so on. These are the projects under way here at present, but it has been said that if an object can be photographed at all or if certain characteristics in a problem can be recorded photographically (for example autoradiographs or sweeps on a cathode-ray tube), then a suitable choice of a pattern measurement instrument may be of considerable use in extracting essential features of interest from the mass of data which are so easily recorded by a photograph. There is little doubt that instruments for pattern measurement will displace the unsupported human observer more and more as the years pass and techniques of measurement and problems being tackled become ever more ambitious and more sophisticated.

As an illustration of the operation of the instrument described here, Fig. 1 shows the result of a line scan across a photograph of the spiral nebula M51. Fig. 2 shows the corresponding appearance of the nebula as observed on the cathode-ray tube of the scanning unit operated in the viewing mode. The variations in grain density across the photograph of the galaxy are very striking. They show how all the information recorded in such a photograph can be transformed into an array of integers which can be permanently stored in the form of the paper-tape print-out and analysed at our convenience according to whatever programme is selected for the computer.

General Remarks

Perhaps the best way to think about pattern measurement is to consider the data, when inserted into the analysis.

Fig 1

Fig. 2

ing computer, as a three-dimensional model of the original photograph or image. The original ordinary two dimensions are preserved by the geometry of the scan and the third dimension is the measured grain density. The function of the programme inserted into the computer is to 'look' at this three-dimensional model in a quantitative analytical way and measure values for parameters of interest. The word pattern reflects the fact that whatever the image is it will have a pattern which can conveniently be described in terms of a series of parameters which can be measured. The weakness of the human eye and brain is their inability to make precise measurements on these parameters and remember them sufficiently accurately for purposes of comparison. However, at least at present, the technique of pattern measurement still depends on the remarkable ability of the human eye and brain to recognize qualitatively the existence of parameters to describe the pattern of interest and thus make it possible to set up the appropriate programme for insertion in the computer.

Although devices for pattern measurement are not new developments, it is probably true to say that fairly recently, since the development of computer-type transistorized circuits and their widespread use, a number of instruments have appeared or are being developed which raise quite exciting possibilities when one considers, for example, the wealth of beautiful photographs obtained with great care and labour and now stored away in laboratories throughout the world. In fact, the development of pattern measurement makes it even more worth while straining to obtain even better photographic records.

We shall be pleased to hear from laboratories, here or abroad, interested in the possibility of collaboration in applying our instruments for pattern measurement to an analysis of the data recorded on existing or projected photographs.

It is our intention, funds permitting, to continue with the development of successive models with even wider facilities, faster speed of scanning and specialized computer and inspection facilities built into the original instruments. In this field, the continued development of genuinely useful instruments depends on the feed-back of experience gained by practical applications.

As a result of such feed-back we have come to the conclusion that, in general, there is no need to consider really large generalized computers even when pattern measurements are being made on complex images which require very large numbers of points to describe them adequately. The use of such computers is really only necessary if one insists on inserting all the information obtained, by scanning a complete image, before commencing the process of analysis. A study of our programme using the mark I instrument suggests strongly that it is worth considering pattern measurement instruments in which one, two or perhaps three lines only are scanned at a time and stored temporarily. This would be followed by immediate analysis using small specialized computer units to extract provisional values for the parameters of interest. These parameters are relatively few in number compared with the total number of points on one or two lines, and the provisional (or line) values of the parameters can be stored for subsequent analysis by a small final computer unit when all the image has been scanned and all the provisional values obtained. This separation of the computer analysis into two parts, provisional and final, is the major difference in our own work and similar efforts in the United States. It does not seem to introduce any great limitations for most images, it avoids the expense of time on large computers which can include the rental of land lines. Perhaps best of all, it opens up the real possibility of relatively inexpensive pattern measurement instruments for individual laboratories where the entire operations and the results are immediately in the hands of individual workers, thus allowing the all-important changes and adjustments which occur in any practical developing project.

This and other points are included in the projected instruments, now being designed here.

We acknowledge the provision of funds by the Department of Scientific and Industrial Research which enabled us to pursue this work, and the award of a D.S.I.R. research studentship to one of us (G. W. McM.). We also thank Mr. Donald Chadney of General Electric Co., Ltd., for his skilful choice of circuitry and components in the design and the successful construction of our present mark I instrument.

OBITUARIES

TWO PIONEERS OF PEST CONTROL

BY strange coincidence the two scientists who had the greatest influence on the development of the initially independent firm of Pest Control, Ltd., died within a few months of one another. Dr. W. E. Ripper crashed in the snow-covered mountains of Greece on March 21, 1965, while on a solo flight, though this fact was not known with certainty until his remains were discovered in June. Dr. E. Parry Jones died in hospital after a long illness, following a longer period of failing health, on June 30.

Both were trained as entomologists. Both gave the best years of their lives to control of pests in agriculture and particularly through their service to the same Company. Their abilities, service and successes were largely complementary. Both brought to bear talents which are essential for the development of a technically based industry. Ripper was essentially an initiator, a creator; sometimes ruthless, sometimes careless under his powerful inner drive to get things going. Parry Jones appeared far more conservative, but this was largely the response of a strongly self-disciplined man to the circumstances he had to face. Ripper's policy had brought the Company into a difficult financial position, and Parry Jones was insistent that, in the next phase of development, novelty and originality had to be kept within the framework of the commercially practicable.

The nature of the untimely death which overtook these men is in a strange sympathy with this difference between them. Ripper's friends had always advised him to forgo his passion for solo flying owing to deterioration of his eyesight, but he was an irrepressible enthusiast for physical as well as mental action, a keen skier and water-skier. He would perhaps have preferred to leave this world suddenly at the height of his powers. Parry Jones, also a keen sportsman in his younger days, had known himself to be in declining health for a long time owing to serious failure of lung capacity. He would not openly admit it, certainly never make a fuss about it, and strongly resented any tendency on the part of his colleagues to do so, but it was clear that he carefully conserved his physical energy and knew that he had to do so. Perhaps the discipline he had to apply to himself helped him to apply a similar discipline to the Company which he nursed round, after its acquisition by Fisons, Ltd., to become Fisons Pest Control, Ltd., from a position of considerable financial loss to one of sound financial profit.

These two men, in their different ways, were leaders in the field of applied science. Without the one the Company of Pest Control would never have started. Without the other it would not have survived the problems of adolescence. The death of both will be a great loss to many.

Dr. W. E. Ripper

Walter Eugen Ripper was born on January 24, 1906, in Austria, the son of Ministerialrat Max Ripper. He was a precocious child and a lot of his stimulus to scientific inquiry came from his father. He once told me that his earliest scientific publication was produced in his teens. He joined the United States Department of Agriculture as entomologist in 1931, working in Europe on the study of natural parasites for the control of pests introduced into the United States. He also acted as consultant to several large seed-growing estates in Austria and Hungary, devising special machinery for spraying unusual crops.

He realized that much good entomological research was being frustrated by the fact that only growers of very expensive crops could afford the necessary spray equipment. In 1938, at a congress in Berlin, he met Sir Guy A. K. Marshall, director of the Commonwealth Institute of Entomology, who was worried by the same difficulty. As a result, Walter Ripper settled in Cambridge, and in 1939 founded Pest Control, Ltd., of which he was managing director and Sir Guy was chairman.

Their aim was to bridge the gap between research and farming by providing a complete service, including machines, chemicals, labour and technical advice. By training, experience and temperament, Ripper was probably better equipped than anyone in Europe for such an enterprise. A man of tremendous physical and mental energy, he worked from 8 a.m. to midnight, seven days a week, driving himself sometimes to the verge of breakdown. A similar pace was expected of his staff, and it is a tribute to his power of inspiration that he was not disappointed.

For many people his drive to apply and exploit obscured an insatiable appetite for knowledge as such. Perhaps I saw more of this facet of a complex man than most. Except in the quiet *tête-à-tête* he would rarely admit ignorance, except, quite clearly, to himself, and then he would always take steps to correct it.

Ripper was always very quick to see the practical application of new research developments. In 1940 he introduced the weedkiller DNOC, which became mainly responsible for the disappearance of the picturesque sheets of red poppies which used to disfigure East Anglian cornfields. His first contract service in England was for the control of aphids by means of a portable nicotine fumigator. This gave a hitherto unobtainable degree of control, and without harm to predacious insects.

When the results of German research became available after the Second World War, Ripper was the first to seize on the idea of systemic insecticides, which could achieve selectivity and access to hidden insects without the need for special machines. His first introduction, 'Schraderin', was also selective, leaving predators to 'mop up' aphids which might survive to give rise to resistant strains. Ripper always thought in terms of 'tailor-made' insecticides, each designed to kill one pest selectively. However, the increasing strictness of regulations for the use of insecticides and the sheer cost of obtaining official approval for a product of relatively limited market forced him to abandon this ideal.

Bringing research results to the farm was very often an engineering problem, and Ripper devised many special machines for the purpose. Even before helicopters became available for civilian use he began to consider their use as air-borne spray machines, and was the first to develop commercial aerial crop-spraying in the United Kingdom.

Shortly after the take-over of his Company by Fisons, Ltd., in 1953, Ripper severed contact with it. It was rather inevitable that the impatient initiator should not be in sympathy with the conservative policy the new management felt necessary to adopt. He joined the Dow Chemical Co., with whom he had had many previous contacts, to found their British subsidiary, Dow Agro-

chemicals, Ltd., in King's Lynn, near to his second wife's large farm at Docking, on which he carried out many experiments. He left Dow to return to his interests in contract spraying, founding Crop Savia, Ltd., in the Sudan, and pursuing further the possibilities of 'robot' aircraft for crop spraying. At the time of his death he was giving much thought to the careful, technically supervised, use of insecticides to avoid undesirable side-effects, a subject that had always been of intense interest to him.

He married first, in 1938, Berthe Siedeck, by whom he had a son and two daughters, and second, in 1952, Nancy Deacon. His son and his second wife intend to continue some at least of his uncompleted work.

Dr. E. P. Jones

Dr. Elwyn Parry Jones, or "P. J.", as he was invariably known to his friends and colleagues, was born in 1907 in Barry, Glamorgan, and educated at Taunton School. He obtained a first-class honours degree in zoology at the University of Wales and continued his education at the Imperial College of Tropical Agriculture, Trinidad, and at the University of Edinburgh, where he gained a Ph.D.

After a short period as a lecturer in the University of Aberdeen, he was seconded to the British South Africa Co. as a research entomologist at the Mazoe Citrus Experimental Station, Rhodesia, where he worked on the control of pests and diseases of citrus crops, until the beginning of the Second World War. After service in the Royal Air Force in Rhodesia, he was invited by Ripper to become the first managing director of a newly formed subsidiary company of Pest Control, Ltd., in Africa, and he was responsible for getting this Company, Pest Control (Central Africa), Ltd., off the ground.

The major activity of this new Company was control of pests of the tobacco crop, but it was also concerned with maintaining public health, and under Parry Jones's guidance it grew and thrived. Being closely associated with tobacco growing, he came to realize that there was an urgent need for a research centre to study improved pest control techniques if the industry was to survive and prosper, and he succeeded in interesting the Rhodesian Government and the Rhodesia Tobacco Association in the formation of the Pest Control Research Scheme, in which his Company was a partner. This arrangement led to the setting up of the present Tobacco Research Board.

Although he was keenly interested in African affairs, he declined an invitation to enter Rhodesian politics, feeling he could serve the country and the pesticide industry better in the Company.

When he returned to the United Kingdom in 1953, he became a member of the board of the parent Company and, shortly afterwards, it was taken over by Fisons, Ltd., and became Fisons Pest Control, Ltd. In the same year, he was made technical general manager, and in this position he was responsible for the research work carried out at Chesterford Park Research Station, where important chemicals used in farming have been developed.

In 1958, Parry Jones was made joint managing director, and in 1961, chairman, and managing director. He was also chairman of Fisons Farmwork, Ltd., a member of the Fisons group main board and of the board of Fisons International Division.

He believed in long-term thinking, with an emphasis on a high level of research, and he considered the well-being of the staff to be of the greatest importance. He attached a high priority to education, and he took a great interest in the instructional courses organized by the Company for farmers, merchants, agricultural workers and advisers.

He saw the Company through its most difficult period. Wasteful marginal activities were pruned. Engineering research and development were abandoned, although the

contracting organization, separately managed as Fisons Farmwork, Ltd., was prosperously maintained. Concentration was on chemicals. Realizing that the search for new chemicals is becoming increasingly difficult and costly, he followed through the initiative of Avison Wormald, the first managing director under the Fisons régime, in negotiating development agreements with other organizations. Most important was the link-up with the Swiss giant, J. R. Geigy S.A., but this was followed by arrangements with Kureha Chemical Industries, Ltd., of Japan, and Boots Pure Drug Co., and successful licences were obtained from others for compounds which his own Company was well fitted to exploit.

Dr. Parry Jones leaves a widow, two sons and a daughter.
G. S. HARTLEY

Prof. K. R. L. Hall

PROF. RONALD HALL'S untimely death on July 14 of this year, at the early age of forty-seven, came as a shock to all who knew him, and not least to his colleagues in the Department of Psychology, in the University of Bristol, where he had been professor since 1959.

During the six years in which Prof. Hall held the chair in the University of Bristol, he had built up an extensive research programme for the comparative study of social behaviour in primates. He was especially interested in early learning and the development of social behaviour in monkeys and baboons. He wrote extensively on the comparison between monkey and ape behaviour, and felt strongly that, since the early writings of people such as Zuckerman and Carpenter, so little had been done to further field studies of a comparative type. He himself was as much concerned with laboratory experiments as with field studies, and he was also concerned with the systematic accumulation of data from all sources to contribute to a picture—detailed in depth—of the behaviour of the animals who come nearest in human evolution to man.

Prof. Hall's work ranged from detailed studies of a specific kind, such as the social vigilance behaviour in the Chacma baboon, to a study of the sexual activity of the same animal, and on to more general efforts to build up an integrated picture, ultimately, of human behaviour.

It was the problems of human behaviour that, in the end, he was working to unravel. His interests in animal studies dated from his period as professor of psychology at the University of Cape Town, which lasted from 1954 until 1959, when he returned to Bristol. Since 1959, he has achieved an international reputation for his work, and has by now published extensively in a wide range of journals. During 1962–63, he was a Fellow at the Centre for Advanced Study in the Behavioural Sciences at Palo Alto, California. He returned to East Africa in 1963 to carry out further ecological and behavioural studies of monkeys and to build more detail into his expanding theoretical framework of behaviour.

Kenneth Ronald Lambert Hall was the only son of Kenneth Lambert Hall, a former acting Governor and Commander-in-Chief of Nyasaland. He was educated at Cheltenham College and at Brasenose College, Oxford, where he took his first degree in Law. During the Second World War, he served in the Middle East and in Germany as a captain in the Royal Artillery, and later as a staff officer. After the War, he returned to Oxford to study psychology, and was awarded the degree of D.Phil. in 1949. In the same year he was appointed head of the Department of Experimental and Clinical Psychology in Bristol Mental Hospitals and was also part-time lecturer in the Department of Psychology at the University of Bristol. During this period his interests were primarily in experimental abnormal psychology, a field in which he built a considerable reputation before his appointment in Cape Town, and his change of primary interest to his ethological work.

He was an exceptional athlete, and as an undergraduate played rugby football for the Oxford University Greyhounds and was awarded a blue for boxing. He continued to play cricket, tennis, squash and golf until his recent illness.

His loss is inevitably a great blow to the development of ethology, and the understanding of animal behaviour, especially as viewed as a basis for a comparison with, and understanding of, human behaviour. He leaves behind him, however, a collection of substantial publications which must in the course of time be brought together into a single collection of his life work.

In 1941 he married Pauline Sophie Assinder, who survives him.
F. H. GEORGE

NEWS and VIEWS

Science Education Officer, British Council :

Mr. D. G. Chisman

MR. D. G. CHISMAN, education officer of the Royal Institute of Chemistry, has been appointed to a new post of science education officer at the London Headquarters of the British Council from January 1966. The Council is increasingly being called on to provide assistance in the expansion and reform of science teaching in schools overseas, particularly in the developing Commonwealth. It now has six science teaching specialists in East and West Africa whose function is to provide assistance with the reform of the curriculum and methods, and the adaptation to local needs and conditions of the results of recent and current British work in this sphere. The new post will serve as a point of reference for the Council's overseas officers, keep them in touch with up-to-date British trends and supply information on new equipment, text-books and audio-visual aids, as well as on new teaching methods. Mr. Chisman, after graduating in chemistry at King's College, London, took a postgraduate certificate of education, and had some years practical secondary school teaching experience before joining the Royal Institute of Chemistry. Since then, as a secretary to the British

Committee on Chemical Education and as a member of both the Consultative Committee for the Nuffield Chemistry Project and the Physical Science Committee of the Association for Science Education, he has been closely concerned with the study of the problems of school science teaching in Britain, and has also been involved with overseas problems as a consultant to the Organization for Economic Co-operation and Development and Unesco.

Zoology in the University of Newcastle upon Tyne :

Prof. A. D. Hobson

PROF. A. D. HOBSON retires from the chair of zoology in the University of Newcastle upon Tyne in September 1966, and is spending most of the year 1965–66 on sabbatical leave. He has been professor of zoology at Newcastle and director of the Dove Marine Laboratory since 1932, first under the title of Armstrong College, then King's College, and, since 1963, as the separate University of Newcastle upon Tyne. During his time at Newcastle he has seen the Department grow from a stage when it consisted of three lecturers, one of them half-time, to its present size of sixteen teaching staff. The closely associated Dove Marine Laboratory has also expanded during this period.

Prof. Hobson's early work was in experimental cytology and he was one of the group of young biologists concerned with the founding of the Society for Experimental Biology. During the Second World War, he worked on nematode physiology, particularly on cultural methods for *Ascaris*; his scholarly work on this subject is well known. Prof. Hobson's other great interest has been marine zoology and, in addition to his directorship of the Dove Marine Laboratory, he has been a member of both the North-East and the Northumberland Sea Fisheries Committees. Prof. Hobson has worked devotedly for the welfare of the Department of Zoology at Newcastle during this period of expansion and change. Many former students and colleagues in zoological work all over the world will wish him every happiness in his retirement.

Prof. R. B. Clark

DR. R. B. CLARK, who has been appointed to succeed Prof. A. D. Hobson, will carry on the tradition of work in marine biology so long established at the University of Newcastle. Dr. Clark started his career as a physical scientist, graduating from Chelsea Polytechnic in 1944 and taking up a post as scientific officer in the Road Research Laboratory of the Department of Scientific and Industrial Research. In 1947 he entered University College, Exeter, to read zoology with Prof. Harvey, gaining his special honours degree in 1950. From 1950 until 1956 he was assistant lecturer at Glasgow, though his tenure there was interrupted by periods spent in the University of Washington, Seattle, and at Berkeley, where he was assistant professor in the University of California from 1953 until 1955. He was appointed lecturer in zoology in the University of Bristol in 1956, and gained his London D.Sc. in 1965. His special interests in marine zoology have centred round the annelids, with particular reference to the polychaetes. Within this group, however, his work has ranged widely. He has contributed substantially to ecology and natural history, and his investigations on polychaete morphology undoubtedly stimulated his interest in the physical factors concerned in the evolution of invertebrates—illustrated in his recent book *Dynamics in Metazoan Evolution* (Oxford, 1965). Dr. Clark is probably best known for his extensive contributions to annelid neurosecretion and neuroendocrinology, where his work has been almost that of a pioneer in annelid physiology. More recently he and his students have published several papers on behaviour in polychaetes, with particular reference to the learning process. His interests will therefore admirably complement and extend those of the active group of zoologists now in the Department.

Metallurgy in Brunel College, London :

Prof. C. Bodsworth

DR. C. BODSWORTH, at present chief physical metallurgist at the Central Research Laboratories of Richard Thomas and Baldwins, Ltd., has been appointed to the newly established post of professor and head of the Department of Metallurgy at Brunel College of Advanced Technology. His early industrial training was with the United Steel Co., Ltd. In 1950, after three years War service with the Royal Corps of Signals, he graduated in metallurgy at the University of Sheffield. He was awarded an M.Met. in 1951 and a Ph.D. in 1957. From 1952 until 1964 he was a lecturer in the Department of Metallurgy in the University of Liverpool. Dr. Bodsworth's scientific interests have centred on metallurgical thermodynamics, and he has written two books on this subject. He has also been actively engaged in investigations of various aspects of phase transformations in ferrous materials.

Assistant for U.S. Medical Research Fellowship Analyses : Dr. E. C. Bracken

DR. EVERETT C. BRACKEN has been appointed assistant to the Chief, Research Fellowships Branch, National

Institute of General Medical Sciences, National Institutes of Health. As professional assistant to Dr. Frederick P. Ferguson, Dr. Bracken will be responsible for conducting analyses of National Institute of General Medical Sciences fellowship programmes to evaluate their effectiveness and to identify scientific areas requiring special emphasis. For the past six years, Dr. Bracken has been at the University of Oklahoma School of Medicine, serving as associate professor in the Microbiology Department since 1960, and as associate professor in the Pediatrics Department and director of the Infectious Diseases Laboratory, Children's Memorial Hospital, since 1959. Dr. Bracken was previously at Vanderbilt University, where he was an instructor and assistant professor in the Microbiology Department of the School of Medicine from 1954 until 1959, and a teaching assistant and instructor in the Biology Department from 1951 until 1954. He is a member of the American Society for Microbiology, the New York Academy of Sciences, the Electron Microscopy Society of America, the American Society for Experimental Pathology, the Southern Society for Pediatric Research, Phi Beta Kappa, and Sigma Xi.

Minister of Power's Advisory Council on Research and Development

MR. F. LEE, the Minister of Power, has appointed Sir Charles Sykes to the chairmanship of his Advisory Council in Research and Development. Sir Charles Sykes succeeds Lord Fleck, who has served as chairman of the Advisory Council since it was constituted in July 1960 and is now retiring. Sir Charles Sykes became a member of the Advisory Council on Research and Development on May 27, 1965. He is managing director of Thos. Firth and John Brown, Ltd., and chairman of Firth-Vickers Stainless Steel, Ltd. He served as a member of the Advisory Council for Scientific and Industrial Research from 1954 until 1956 and as a member of the Research Council of the Department of Scientific and Industrial Research from 1962 until its dissolution in March 1965. Lord Fleck served as chairman of the Minister of Power's Scientific Advisory Council from 1958 until 1960.

The terms of reference of the Advisory Council are:

- (1) To advise the Minister of Power on research and development in relation to his statutory duty of securing the effective and co-ordinated development of coal, petroleum and other sources of fuel and power in Great Britain, and of promoting economy and efficiency in the supply, distribution, use and consumption of fuel and power, whether produced in Great Britain or not.
- (2) To advise the Minister of new scientific and technical knowledge or applications of knowledge throughout the world, which in the opinion of the Council should be taken into account in the performance of his statutory duties.
- (3) To keep the whole field of fuel and power under continuous review with the object of identifying problems needing research and development and advising the Minister of these problems with the view of discussion with the industries concerned.

Other members of the Council are: Captain (E.) W. Gregson (deputy chairman), Mr. M. A. L. Banks, Prof. P. M. S. Blackett, Sir Charles Cawley, Mr. H. E. Collins, Sir Kenneth Hutchison, Sir Harry Melville, Mr. R. V. Moore, Dr. L. Rotherham and Prof. M. W. Thring. The assessors are Dr. E. Lee, Mr. H. T. Ramsay and Mr. H. S. Stephenson.

University Entrance Requirements in Britain

THE third edition of *A Compendium of University Entrance Requirements for First Degree Courses in the United Kingdom, 1965*, which has been compiled from material provided by the universities to the Committee of Vice-Chancellors and Principals, has been extensively revised and is more comprehensive than either of its

predecessors (Pp. 219. London: The Association of Commonwealth Universities, 1965. 11s. 6d.). Its coverage of combined honours courses has been extended and also expanded to include details of the entrance requirements of the ten colleges of advanced technology and the Heriot-Watt College, all of which are to have the status of university institutions. In addition, the tables include for the first time the entrance requirements of the Scottish universities, expressed in terms of the General Certificate of Education. In this edition the course requirements of the principal full-time first-degree courses offered by the universities of the United Kingdom are set out in terms of the General Certificate of Education in eighty tables, covering single honours, combined honours and general degree courses. The information provided in the text is supplemented by a self-indexing list of combined honours courses offered by fewer than four universities, and by notes on particular institutions the courses and requirements of which do not fall into the usual pattern. The compendium is not an official publication of the universities concerned and cannot be regarded as superseding their own publications, which are the ultimate authorities. The tables indicate that many universities formally require only two Advanced Level passes in the General Certificate of Education for most courses in arts, law and social studies (and for a few in science and technology), whereas other universities formally require three. Most candidates present three or more, which many university selectors regard as preferable. However, the pattern of academic entrance requirements may still be unduly complex, and it has been agreed that consideration of ways in which general and course requirements might be simplified will be one of the first tasks to be undertaken by the Standing Committee on University Entrance, a delegate body, established in June 1965, representative of the universities of the United Kingdom.

La Trobe University, Melbourne

LA TROBE UNIVERSITY, which will be the third University in the Melbourne metropolitan area, was established under an Act of the Parliament of Victoria on December 9, 1964. The site for the new University is an undeveloped tract of some 500 acres about 8 miles north-east of the city centre. Planning of the site works and initial buildings is proceeding and the University will open in March 1967. Planning and development of the University, in the present preparatory stage, are controlled by an Interim Council of twenty-five members under the chairmanship of J. R. A. Glenn, chairman and managing director of I.C.I.A.N.Z., Ltd. The principal officers appointed so far are: *Vice-Chancellor*, Dr. D. M. Myers (at present dean of the Faculty of Applied Science, University of British Columbia); *Librarian*, D. H. Borchardt. Applications have been requested for foundation chairs in English, history, philosophy, a modern European language, economics, sociology, politics, mathematics, physics, chemistry and biology; but so far no appointments have been made. The academic work of the new University is to be organized in schools of related disciplines. Each school will be the functional unit for teaching, research and administration in the disciplines which it embraces. Its field will be wider than that of a traditional department but narrower than that of a faculty. Student activities will be centred on colleges that will provide study, recreational, social, dining and some tutorial facilities for all members, and residential facilities for a minority of the members. All members of the academic, library and administrative staffs will also belong to the colleges.

Museums Journal

THE *Museums Journal* (65, No. 2; September 1965. 15s.) includes a number of interesting papers, in addition to a full report of the annual conference of the Museums Association in Dublin in June 1965. Dr. S. Dillon Ripley,

as secretary of the Smithsonian Institution, describes the Institution as a great museum centre; Mr. C. Douglas Deane gives details of the Field Museum and Nature Trail in Northern Ireland; and Mr. H. Wakefield gives much useful information to curators concerning the availability of purchase grants from the Victoria and Albert Museum, London, to provincial museums. Mr. N. Cook, president and keeper of the Guildhall Museum, London, dealt with many subjects in his address, chiefly those concerning the Museums Association in relation to Government grants. Dr. A. T. Lucas, director of the National Museum of Ireland, developed the theme of the role of the National Museum in the study of Irish social history, and Mr. R. Rowe spoke on "Art Museums and the Idea of Progress". At the annual meeting, Sir Frank Francis, director of the British Museum, was elected president for 1965-66, when the annual conference will be held in Sheffield during July 4-9.

British Museum : Department of Western Asiatic Antiquities

THE British Museum regrets to state that the Assyrian sculpture, mostly of Sennacherib and Ashurbanipal, from their palaces at Ninevah, which has been exhibited in the Assyrian Saloon and the Assyrian basement, will be for the most part unavailable for examination until further notice, owing to the rebuilding of the Assyrian Saloon and the insertion of a new floor.

Storage of Books

AN essay by P. W. Plumb, entitled "Central Library Storage of Books", which was awarded the Sevensma Prize, 1962, has been issued as *Library Association Pamphlet No. 24* (Pp. 57. London: Library Association, 1964. 16s.; L.A. members 12s.). It reviews experience gained in the United States, Britain and elsewhere, including the use of microfilm. There are brief appraisals of methods used at the British Museum Newspaper Library, the Storage Library of the University of London, the National Central Library and the National Lending Library for Science and Technology, as well as at the Bibliothèque Nationale Storage Library, and, in the United States, the New England Deposit Library, the Midwest Inter-Library Centre, and the Medical Library Center of New York. Mr. Plumb commends the systems of the National Central Library and the National Lending Library for Science and Technology, and concludes that a national scientific and technical lending library and one for the humanities and sociology in each country with similar but perfected aims and techniques would go far to solving the space problems of libraries. Certainly this suggestion, if applied, would help in avoiding the major disabilities apparent in many existing schemes and proposals.

Directory of Indian Scientific Periodicals

THE *Directory of Indian Scientific Periodicals, 1964*, with its 725 entries listing periodicals current to the end of 1963, including annual reports of scientific and technical institutions and other learned societies, is intended as a first step towards consolidating and servicing scientific communication in India (Compiled by G. K. Arora, S. Dutta, D. N. Gupta and H. N. Rangachar. Pp. 133. Delhi: Indian National Scientific Documentation Centre, 1965). The *Nisfor Guide to Indian Periodicals*, published at Poona in 1955-56, and a cyclostyled list of Indian scientific periodicals issued in 1960 laid some foundation for the present *Directory*. The entries are arranged according to the Universal Decimal Classification and there is an alphabetical index of titles. The periodicals are mainly in English, about half a dozen being bilingual with English as one language; there are 60 periodicals in Indian regional languages (33 in Hindi) and one in French. The *Directory* is well printed and well set out.

Volcanological Research in Britain

ON behalf of the Volcanological Research Committee of the Royal Society, the terms of reference of which are "to encourage, promote and co-ordinate the comprehensive study of volcanicity . . .", a booklet has been published to record the scope of researches being undertaken at present by universities and other scientific institutions in Britain on modern and ancient volcanoes (*United Kingdom Volcanological Research, 1965*. A summary of current volcanological studies with provisional plans for future years. Pp. 55. London: The Royal Society, 1965). The extent of the studies recorded is wide, embracing work at about a hundred localities outside the British Isles, described in close on 150 recent papers (inclusive of some reports of researches in experimental petrology). It is hoped to publish a further edition of the booklet in about two years' time when attention will be restricted to current investigations on Tertiary and Recent volcanicity.

Age Determinations of North American Rocks

A COMPILATION of the radiometric ages determined for rocks of the North American continent, complete up to May 1964, has recently been published by the Committee on Nuclear Science of the National Academy of Sciences—National Research Council in Washington (Publication 1276: *Geochronology of North America*. Nuclear Science Series—Report No. 41. Pp. v+315. Washington, D.C.: National Academy of Sciences—National Research Council, 1965. 6 dollars). In it, a brief introduction to the present status of geochronological methods, by Dr. G. W. Wetherill, is followed by a 270-page tabulation of results listed on a regional basis and by a bibliography of 144 items. The oldest well-dated rocks in North America bear ages of about 2,500–2,800 million years, and are found in an apparently continuous belt extending from Quebec through Ontario, Manitoba, Minnesota, North Dakota, Montana, and into Wyoming, as well as in the Great Slave Lake area of the North-West Territory. They are apparently much younger than the most ancient formations of southern Africa and of arctic Russia. Extensive recent data supplementary to the results in the American compilation have been published contemporaneously by the Geological Survey of Canada and are accompanied by a report by Dr. C. H. Stockwell which proposes a new time-stratigraphic classification and nomenclature for the rocks of the Canadian shield (Paper 64-17. Parts I and II. *Age Determinations and Geological Studies*. (I) Pp. iv+126. 75 cents. (II) Pp. iv+29. 75 cents. Ottawa: Queen's Printer, 1965). In this, the Archaean and Proterozoic are each identified as eons, with the latter divided into the Aphebian, Helikian (Palaeohelikian and Neohelikian) and Hadrynian eras, the lower boundaries of which are respectively marked by the Kenoran (2,390 m.y.), Hudsonian (1,640 m.y.; Elsonian at ?1,280 m.y.), and Grenville (880 m.y.) orogenies.

Soil Micro-fauna

THE formation of humus is a most important matter to foresters, not only because it helps to maintain proper conditions for tree growth, but also because it may bring about improvements to the quality of the trees and give greater productivity to the site. A big part is played by oribatids in the breakdown of the litter and its conversion into humus, and members of this super-family of the Acarinae occur in very large numbers in the soil fauna. In *Contribution à l'Etude Ecologique des Oribates de la Litière dans une Forêt de Moyenne-Belgique*, by Philippe Lebrun, we not only have an example of a very fine piece of research carried out in 13 months of field work, but also results presented in a full and yet concise manner, and set out with proper reference to the other factors affecting the biocenose (Institut Royal des

Sciences Naturelles de Belgique. Memoire No. 153. Pp. 96. Bruxelles: Institut Royal des Sciences Naturelles de Belgique, 1965). The published account is divided into three chapters. The first is an account of the locality factors. The research was carried out in an oak-wood on the south-eastern slopes of a small valley near Louvain in central Belgium in 1961–62. Information is given of the vegetation, soil, local climate, the water-holding capacity of the soil and the evapotranspiration. The second chapter is devoted to the synecology of the oribatids with the view of discovering the bonds existing between different groups of them. The final chapter deals with the autecology of the oribatids found on the site. The forester recognizes the great importance of these minute members of the animal kingdom, but it is not always remembered in what quantities they occur. In a Belgian oak-wood it is estimated that there are about 75,000 individuals per square metre of the upper soil and humus layers and even up to as many as 300,000 per square metre. Thus, their numbers alone present some difficulty to the research worker who, in this case, had to contend with 48 species in a sample population of 85,000 individuals. Philippe Lebrun has not only clearly described his fine piece of research but he has also taken into consideration, as is very proper but not always done, the various factors of the vegetation, soil and climate which contribute to the biocenose. Thus, the danger in such a work of omitting some important factor affecting the result has been avoided. The numerous histograms and graphs make for easy understanding of the various components of the investigation. Nothing seems to have been forgotten: for example, there is a histogram showing the precipitation reaching the soil compared with the actual precipitation. This is but one example of the detail to be found in a work which will be acclaimed by foresters and others interested in the soil micro-fauna.

Oil Pipeline over the Alps

It may not be generally realized that work is in progress on the colossal project of constructing a 40-in. diameter, 300 miles long, Trans-Alpine oil pipeline to convey oil from the Adriatic to the heart of Germany, as so far this scheme has received relatively little publicity. To a brief extent, this has now been remedied by an article entitled "Pipeline Over the Alps" (*Esso Magazine*, Esso Petroleum Company, London, Summer 1965). The route lies from Trieste, by Udine, Lienz, Kitzbuhel, Kufstein, Rosenheim, east of Munich to Ingolstadt. It necessitates the construction of three tunnels under the Alps, one known as the Plöcken Tunnel, between Udine and Lienz; one known as the Felber Tauern Tunnel, and another as the Hahnenkamm Tunnel, both between Lienz and Kitzbuhel. These are indeed major engineering feats in themselves, and the photographic illustrations included in the article, together with a panoramic map in colour, make this abundantly clear. This project will ultimately include the construction of a branch pipeline just north of the Plöcken Tunnel to link up with the Austrian State Refinery near Vienna. The Trans-Alpine pipeline is a venture in which several oil companies are taking part and in which the Esso Petroleum Company has the largest interest. However, because the pipeline has to pass through three separate countries, three separate companies have been formed for constructional and operational purposes in their respective areas. These companies are Deutsche Trans-Alpine Oelleitung G.m.b.H., Trans-Alpine Oelleitung in Österreich G.m.b.H., and Società Italiana per l'Oleodotto Trans-Alpino S.p.A. The German company is the co-ordinating company. Among the many practical problems concerned with such a project, apart from tunnelling and mechanical excavation in the high Alps, are the necessity to dredge the harbour at Trieste so that it can eventually accommodate oil tankers of 160,000 dead weight tons; setting storage tanks there on piles because

available land is a rocky hill site; construction of several thousand feet of piers into the Adriatic, so laying many connecting pipelines to the tank-farm. Involved also in the scheme is the building of five separate pumping stations, each equipped with two 4,000-horse-power electric centrifugal pumps required to lift hundreds of thousands of tons of oil from sea-level to one of the highest points at Felber Tauern. It would appear that completion of the main works and expectation that the new pipeline will be 'on stream' are likely in about two years' time, which will be a most remarkable achievement if realized.

University News:

Aberdeen

Dr. H. J. EVANS has been appointed to the newly created chair of genetics. The following lecturers have also been appointed: Dr. P. G. Jarvis (botany); J. F. Robbie (engineering); Dr. J. B. Wilson (geology); Dr. G. F. Burnett (agriculture).

Manchester

Dr. D. M. McDOWELL has been appointed to the chair of hydrodynamics and hydrology. The following lecturers have also been appointed: Dr. G. N. Smith (chemistry); W. McLewin (mathematics); Dr. A. R. Mainwaring (pathology); Dr. H. A. Lee (medicine).

Birmingham

THE following appointments have been made: *Lectureships*, Dr. C. J. Hooke (mechanical engineering); V. L. Moffat (engineering production); Dr. B. Sklarz (chemistry); Dr. J. H. Coote and Dr. A. R. Tindall (physiology); Dr. I. D. Green (medicine); Dr. N. R. Ling (experimental pathology); *Senior Fellowship*, Dr. J. M. Whittaker (pure mathematics); *Research Fellowships*, P. F. Adams, C. G. Drury and I. T. Franks (engineering production); K. J. Blackburn, C. J. Chesterton and J. Kendrick-Jones (biochemistry); S. F. Campbell, Dr. W. B. Hollyhead and M. A. Salam (chemistry); Dr. M. K. Das and Dr. M. M. Sadek (mechanical engineering); G. Immirzi and Dr. D. H. Lyth (mathematical physics); J. Jafar (physics); M. J. Pemberton (minerals engineering); M. W. Stanley (physical metallurgy); Dr. P. S. Hasleton (pathology); Dr. C. C. McCormick (experimental pathology).

Lalor Foundation Grants for 1966

THE Lalor Foundation has announced the programme of awards for 1966, which it is offering for support of research on the fundamental biochemical and physiological mechanisms concerned with fertility and the early stages of reproduction in various forms of life. The objectives are to further the knowledge and understanding of the basic phenomena involved and to extend and develop the possibilities for effective regulation and control. The awards are open to all nationalities and may range up to 8,000 dollars a year, depending on the scope and duration of the projects approved. Preference will be given to younger members of university and college faculties and staff, with an upper age-limit of forty-one years. The work may be carried on at the applicant's own institution or elsewhere. The Foundation will also grant post-doctorate summer or short-term research awards at the Marine Biological Laboratory at Woods Hole, Mass., or elsewhere for appropriate projects in the fields specified. These awards will normally not exceed 1,200 dollars for a single man or woman, 1,400 dollars for a married man working at his home institution, and 1,550 dollars for a married man with a principal programme at another institution. Further information and application forms can be obtained from the Lalor Foundation, 4400 Lancaster Pike, Wilmington, Delaware. The final date for receipt of executed applications, complete with supporting data, is January 15, 1966. Notification of appointment will be on or before March 15, 1966.

European Society for Comparative Endocrinology

At the third meeting of European comparative endocrinologists, held in Copenhagen during August 2-5, it was decided to form a European Society for Comparative Endocrinology. The following were elected as the first officers and council of the Society: *President*, H. Helle (Bristol); *Vice-President*, M. Fontaine (Paris); *Secretary and Treasurer*, P. G. W. J. van Oordt (Utrecht); *Honorary Editor of the Proceedings of the Society*, E. J. W. Barrington (Nottingham); *Council Members*, H. Herlant-Meewis (Brussels), C. Barker Jørgensen (Copenhagen), M. Lüscher (Bern), V. Mazzi (Turin) and V. J. A. Novák (Prague). Those interested in the aims of the Society are invited to write to the Secretary, Zoological Laboratory, State University of Utrecht, Janskerkhof 3, Utrecht.

Announcements

Dr. H. E. HUXLEY has been awarded the first William Bate Hardy Prize of the Cambridge Philosophical Society for his work on the structure of muscle. The William Bate Hardy Prize was established in 1964 by the Cambridge Philosophical Society to commemorate the centenary of the birth of Sir William Bate Hardy, a Fellow of the Society from 1889 until his death in 1934. It is awarded for the best original memoir, investigation or discovery by a member of the University of Cambridge in connexion with biological science published during the three years immediately preceding the award. The present value of the Prize is £200.

A SHORT course for librarians and information officers on "The Trade Literature Collection", arranged by Aslib, will be held at Aslib during November 25-26. Further information can be obtained from the Education Officer, Aslib, 3 Belgrave Square, London, S.W.1.

A SEMINAR on "Creativity in Science", arranged by the Science of Science Foundation, will be held at the Foundation on December 8. Further information can be obtained from the Science of Science Foundation, c/o the Ciba Foundation, 41 Portland Place, London, W.1.

THE second Australian conference on "Hydraulics and Fluid Mechanics" will be held at the University of Auckland during December 6-12. Further information can be obtained from the Convenor of the conference, School of Engineering, Ardmore College Post Office, University of Auckland, Auckland.

THE 1965 International Building Exhibition will be held at Olympia, London, during November 17-December 1. During the Exhibition, five conferences will be held: building for people; system building—can it be economic?; exporting building materials; the important role of building component manufacturers; the change to metric. Further information can be obtained from the Conference Secretary, the Building Exhibition, 11 Manchester Square, London, W.1.

A MEETING of the Biochemical Society will be held in the University of Manchester during November 11-12. The programme will include a colloquium on "Biosynthesis in Micro-organisms: Genetic and Environmental Factors"; a discussion meeting on "Biochemistry and Industry"; and the Colworth Medal Lecture on "The Role and Control of the Glyoxalate Cycle in *Escherichia coli*", to be delivered by Prof. H. L. Kornberg. Further information can be obtained from Prof. K. S. Dodgson, Department of Biochemistry, University College of South Wales and Monmouthshire, St. Andrew's Place, Cardiff.

ERRATUM. In Table 4 of the article entitled "Identification of Dinitro-octylphenols in Certain Commercial Fungicides", by Dr. A. H. M. Kirby and L. D. Hunter, which appeared on p. 189 of the October 9 issue of *Nature*, the last five lines should be amended to read as follows:

7-41(7g)	7-37g	7-26m	7-15(6 8se)	7-28(7 5t)	1-CH
1-91s {	1-89s {	1-85s	1-90s {	1-87s {	1-CH ₂
		1-88s			5-H
					3-H

HORTICULTURAL SCIENCE AT THE UNIVERSITY OF READING

THE diamond jubilee of the Horticultural Education Association was marked by a conference at the University of Reading during September 6-9. The object of the conference indicated by the theme, "Horticultural Science at the University of Reading", was to bring together contributions from a number of the branches of science that find a meeting point in the technology of horticulture. It was part of the success of the conference that it directed attention to the importance of border-line research between disciplines and to the desirability of combining pure and applied research.

Contributions from the Department of Horticulture were concerned with plant physiology and plant protection. Prof. O. V. S. Heath discussed methods of measuring stomatal aperture and pointed to the importance of a knowledge of stomatal physiology in attempts to control water loss from crop plants. Dr. H. Meidner demonstrated a portable and relatively cheap instrument for measuring the water content of soils by determination of their heat conductivity. One of the main advantages of the method was that the probe employed, unlike the porous block used in other techniques of soil moisture determination, did not have to equilibrate with water in the soil.

Papers by Dr. D. Vince and Dr. G. P. Harris were concerned with the photoperiodic control of flowering in long-day plants. Dr. Vince described experiments with different strains and species of *Lolium* that demonstrated a changing sensitivity to red and far-red radiation during a 16-h night. It appeared that in order to produce a maximum promotion of flowering by interruption of the night with red light, the timing of the interruption had to be varied according to the species or strain of *Lolium* used. The potentialities of detailed investigations of the photoperiodic responses of plants of horticultural importance were underlined in the paper by Dr. Harris on flowering in the glasshouse carnation. Out of a number of photoperiodic treatments tested, the use of lighting from tungsten-filament bulbs throughout the night was found to be most effective in promoting flowering under winter conditions. Applications of this observation to commercial practice were discussed. Dr. H. F. van Emden bridged the gap between plant physiology and entomology in a discussion of plant-insect relations. Results were presented indicating the role of the nitrogen status of the plant and particularly the soluble-nutritional content in controlling rates of aphid multiplication.

The Agricultural Research Council Unit of Flower Crop Physiology, which, under the direction of Prof. O. V. S.

Heath, is attached to the Department of Horticulture, was represented both in a comprehensive demonstration of equipment and in a paper read by Dr. A. P. Hughes. The main item of equipment in the Unit is 9 (later to be 12) growth cabinets designed by the National Institute of Agricultural Engineering and housed in a special hall with controlled ventilation. Dr. Hughes described the use of this equipment to investigate interactions of light intensity, temperature and carbon-dioxide concentration. He also presented results of experiments demonstrating effects of photoperiodic treatments on leaf expansion in a variety of plants and discussed the use of such treatments under conditions where light intensities are limiting to growth in dry weight.

In a contribution from the Department of Physiological Chemistry, Dr. K. A. Hassall discussed problems encountered in the use of crop protection chemicals including questions of toxicity, persistence and selectivity. Experimental results showed how the persistence and effectiveness of a pre-emergence weed-killer could vary with the amount of rain falling after application.

From the Department of Agricultural Botany there were papers on physiological ecology and plant breeding and genetics. Prof. A. H. Bunting described work on the water relations of plants growing on soils of the chalk downs near Reading and demonstrated the capacity of the chalk to retain water by reference to its pF -moisture content curve. The pore size distribution derived from this curve was shown to be similar to a distribution based on direct measurements of pore sizes in electronmicrographs. Dr. J. K. Jones and Mr. G. D. Rowley in contributions concerned with plant breeding both emphasized the value of using wild species as sources of genetic variation. Dr. Jones presented evidence that the sets of chromosomes in all species of strawberries were homologous, that it was possible to produce many inter-specific hybrids and to induce polyploidy and therefore to use most, if not all, of the species in breeding. Mr. Rowley showed how the derivation of cultivars of rose could be traced by crossing supposed parent species and underlined the importance of making provision for the conservation of species and cultivars that might not be of immediate commercial value.

This report indicates the varied nature of the papers presented; but the contributions had in common an immediate or potential value to horticulture. The conference provided members with the opportunity to examine the role of the University in the development of this subject.

G. P. HARRIS

THE WORLD HEALTH ORGANIZATION, 1964

A REMINDER that the control of communicable diseases is "still the most important health challenge facing mankind" is given by Dr. M. G. Candau, director-general of the World Health Organization, in his annual report for 1964*.

It is not, therefore, surprising that, notwithstanding the new developments in the work of the World Health Organization, the chapter on communicable diseases remains the longest in the volume. While some diseases have declined in public health and economic importance, others are still obstinate or present new problems.

* Official Records of the World Health Organization, No. 139: The Work of WHO. Annual Report of the Director-General to the World Health Assembly and to the United Nations. Pp. xiv+240. (Geneva: World Health Organization; London: H.M.S.O., 1965.) 4 Sw. francs; 6s. 8d.; 1.25 dollars.

Dr. Candau points to the increasing incidence of plague the heavy toll of cholera and smallpox, the continuing problems of malaria and tuberculosis, the upsurge in the incidence of syphilis and gonorrhoea. He lists, as the three main obstacles to effective control, lack of knowledge, insufficient international support for the Organization and financing of campaigns and, most formidable of all, lack of adequate health services in the countries most affected. Lasting success can be achieved only through the establishment of permanent and effective health services applying national health plans.

The experience of the Organization has shown that quick results cannot be expected; the countries most in need of assistance for national health planning are those where

statistics are scanty, the shortage of trained staff acute, and where multiple health problems compete for priority. Nevertheless, Dr. Candau is able to report progress in comprehensive health planning in a number of countries, for example, Africa, Latin America, and Asia—the areas presenting the greatest problems.

In campaigns against many of the communicable diseases, the use of research is a valuable adjunct to the work in the field. In its medical research programme, the Organization draws on the advice of leading experts in many special fields and now has the collaboration of laboratories in all parts of the world. The lists of the reference laboratories of the World Health Organization and of scientific meetings during the year provide some indication of the scope of the programme. The research programme is by no means restricted to the communicable diseases. The report contains, for example, accounts of the present studies on cancer (including the possible relation between viruses and cancer), cardiovascular diseases, and human genetics—a new field of activity for the World Health Organization (see *Nature*, 208, 230; 1965). The importance of immunology is stressed, and achievements are mentioned in the Organization's relatively new programme of immunological research, particularly in relation to parasitic diseases—a hitherto largely unexplored area of immunization in which further research has been planned on the advice of an expert committee.

Other topics dealt with in the "General Review", constituting Part 1, include malaria eradication, environmental health, public health services, health protection and promotion, education and training, biology and pharmacology, health statistics, publications, information,

and administration and finance. A final chapter outlines the work done in co-operation with the United Nations and related agencies, and with non-governmental organizations.

Part 2 deals with the health problems and programmes in each of the Organization's six regions—Africa, the Americas, south-east Asia, Europe, eastern Mediterranean and western Pacific. In each chapter, broad surveys of work in the region concerned are complemented by detailed descriptions of some of the typical projects in which the Organization is giving assistance. They include the preparation of a plan to be financed under the United Nations Special Fund for the metropolitan area of Accra in Ghana; the improvement of nursing education and services in Guatemala; a project in south-east Asia to increase the local production of freeze-dried smallpox vaccine, which is essential for the successful pursuit of the smallpox eradication campaign in tropical countries; malaria eradication in Pakistan; and, in the western Pacific region, the first regional conference of deans of medical schools. For the European region, one of the projects described is a symposium in Moscow on the toxicology of drugs and methods of ensuring the therapeutic safety of drugs.

The list of current projects contained in Part 3 is a reflexion of the Organization's varied activities and of their adaptation to the particular requirements of countries in the various regions.

Information given in the annexes includes membership of the Organization, its executive board and expert committees, the budget, the secretariat, fellowships, awards under the medical research programme, and the reference centres.

A COMPARISON OF EUROPEAN HEALTH SERVICES

ALL European countries have some form of administrative arrangements to deal with environmental health; for example, housing standards, water purity, sewage and refuse disposal, and food hygiene. Modern life has brought into prominence new environmental problems, largely arising from industrialization and urbanization. A special monograph on health services in Europe was prepared for the European Conference on Public Health Administration held by the World Health Organization Regional Office for Europe in Zagreb, Yugoslavia, in June 1964*.

Air pollution is one cause for concern. Already most industrialized European countries have special regulations giving local authorities a measure of control over industrial emissions. Czechoslovakia and other countries have established standards for the control of health hazards from this source, while in the Federal Republic of Germany there are trade regulations and a Civil Code. In the U.S.S.R., the Institute of General and Communal Hygiene of the Academy of Medicine is carrying out research on air pollution in the principal industrial centres. Maximum permissible concentrations for 20 pollutants commonly found in the air of industrial cities have already been worked out. In the United Kingdom, smokeless zones are being established under a Clean Air Act. In Spain, provision is made for air disinfection in hospitals and certain clinics, and special legislation has been created covering unhealthy and dangerous gases and smoke.

Noise, as a public health problem, is also being tackled. Bulgaria has imposed restrictions on it in industry and in transport. In Spain, what are called "silence campaigns"

have been carried out in the larger towns, where noise elimination is the concern of the municipal authorities and industrial boards. The U.S.S.R. has set up a Central State Health Inspectorate to deal with problems concerned with noise.

In many European countries, in accordance with the requirements of the International Commission on Radiological Protection, radiation hazards have been the subject of precautionary measures. In the United Kingdom, watch is kept on radioactivity in the air and in the soil by the Atomic Energy Authority in collaboration with the Medical and Agricultural Research Councils, and the Ministry of Housing and Local Government supervises the disposal of radioactive material. In Denmark, under an Act which has been in force since 1953, no radioactive material may be manufactured, owned or imported without special permission from the National Health Service, acting on behalf of the Ministry of the Interior; the Act lists safety precautions covering transport, storage, and use. Finland's Radiation Protection Act controls X-ray and other radiation installations, and Norway also has regulations covering the protection of personnel and the transport of radioactive material. Similar provisions exist in Czechoslovakia, Hungary, Ireland, Switzerland and Turkey. In the Federal Republic of Germany, the Max-Planck Institute of Biophysics carries out systematic investigations of radioactivity in ground water, rivers, and soil, and the meteorological stations make regular measurements of radioactivity in the atmosphere.

To-day, all countries in Europe have some arrangements for controlling the spread of infectious diseases, and the incidence of most of them has been on the wane for some time. Tuberculosis, however, still remains a cause for great concern. In the Federal Republic of Germany, several *Länder* have legislation providing for regular

* A limited number of copies of this document (reference *Euro* 268-4) are available to persons officially or professionally interested in the subject, on request from the World Health Organization Regional Office for Europe, Copenhagen

chest X-ray examinations. One result of this approach has been the discovery that the percentage of undiagnosed cases of tuberculosis is higher among older people. In Norway, the Ministry of Social Affairs has the power to enforce X-ray screening of part of, or all, the population, as well as to test for tuberculosis, and to give B.C.G. vaccination. The radiography services in Italy are aimed at detecting not only tuberculosis but also other respiratory diseases, cardiovascular diseases and lung tumours. Compulsory B.C.G. vaccination is practised in some countries, such as Yugoslavia. Tuberculosis is notifiable in most European countries, but not in The Netherlands, Portugal or Romania.

There is a good deal of variation in the regulations regarding immunization against such infections as smallpox, diphtheria, tetanus, and whooping cough. Smallpox vaccination is compulsory in most European countries, and it is prescribed by the International Sanitary Regulations. It is required, for example, in Czechoslovakia, Hungary, Turkey, the U.S.S.R., and Yugoslavia, but it is not compulsory in the United Kingdom. In Yugoslavia immunization against diphtheria and tetanus is also obligatory.

Some communicable diseases are confined to particular areas. In Europe, for example, trachoma is endemic only in the Mediterranean countries. Spain carries out trachoma control through a network of clinics helped by the World Health Organization and the United Nations International Children's Emergency Fund; in Greece, treatment and control are carried out through a chain of anti-trachoma dispensaries. In Italy provincial anti-trachoma associations have been set up in co-operation with public and school dispensaries, specialized hospital services, and district health visitor services. Turkey is gaining control over the disease through an increase in the number of dispensaries. Yugoslavia has made a successful attack on its foci of trachoma: senior medical students have carried out surveys among people in affected areas, and

suspects are called for examination by specialists. Typhus, formerly widespread in eastern Europe, is now under control, and in Romania success has been achieved through co-operation between Government, the sanitation and epidemiological services, and the public. Public instruction in control methods has been given by trade unions, co-operative services and the Red Cross organizations.

An important development in the control of communicable disease has been the recognition of the part that veterinary science can play against zoonoses. In Italy, for example, there is a Veterinary Division within the Ministry of Health, which deals with such diseases as brucellosis, canine rabies and glanders. In Hungary, the *sanepids* (sanitary and epidemiological stations) have established programmes for brucellosis control in agricultural undertakings, helminthiasis control among schoolchildren, and ancylostomiasis control among miners. In Spain close co-operation is maintained between the health authorities and the veterinary services in the control of brucellosis, tuberculosis transmitted by animals, and other zoonoses. Laboratory facilities, an essential element in the control of communicable diseases, are provided by the local *sanepids* in most eastern European countries, at the health offices in the Federal Republic of Germany and at the universities and hospitals in Austria. In England and Wales there is a national network of laboratories, operated on behalf of the Ministry of Health.

In Yugoslavia, the institutes of hygiene undertake special research projects, as well as routine examinations of public health specimens. This arrangement has been particularly helpful in special field campaigns against endemic syphilis and trachoma.

Other preventive services described in the monograph include food and drug control, maternal and child health, school health, occupational health, mental health and alcoholism, care of the aged, dental care, and health education.

ANTARCTIC AERONOMY AND ICE SHEETS

DURING the past ten years the amount of scientific data available from Antarctica has increased by an order of magnitude. The position has at last been reached when it is stimulating and useful to summarize knowledge in many disciplines in the form of maps. The United States, the U.S.S.R. and the United Kingdom all have projects in hand to publish scientific atlases of Antarctic Research.

The Antarctic Map Folio Series is being published by the American Geographical Society under a contract with the National Science Foundation. The price is most reasonable and indicates that considerable and well-justified financial support has been given by the National Science Foundation. The form of publication and the contents have been based on replies to lengthy questionnaires sent to many interested scientists. The series will consist of about twenty folios, each devoted to one subject or scientific discipline. Each folio consists of a series of maps or diagrams printed on one side of sheets usually 17 × 22 in. and several pages of text of 17 × 11 in.; some plates are also of this size. Each folio series is contained in a light cardboard folder. Four colours are used in the production of maps.

The first folio* deals with aeronomy and has been produced by members of the AVCO Corporation, Wilmington, Massachusetts. A brief text explains the purpose of the observations and the method of compilation. It also

includes brief outlines and maps of some data relevant to conjugate points and to the southern auroral zone. The definition of magnetic B and magnetic L values which is given is somewhat involved for the layman. The plates all show ionospheric conditions for 1957 or 1958, the period of maximum sunspot activity. The maps on a scale of about 1:100 million show the following parameters: f_oE and f_oF_1 at 0000 and 1200 U.T.; f_oF_2 at 3 h (U.T.) intervals for winter, equinoctial and summer conditions, the percentage of time that $f_oE_s > 5$ Mc/s, and magnetic B and L values at 0, 100, 200, 500, and 1,000 km. The folio should be useful for general reference purposes for scientists in contact with ionospheric problems, but a non-specialist seeking a general appreciation of this work would learn more from a general review article.

The second folio† on the physical characteristics of the Antarctic ice sheet has been compiled in university and other institutes. It deals with several topics of general geographical interest. The Antarctic maps at 1:13.6 million are at a scale suitable to the detailed knowledge of many regions. Use of four-colour printing brings out general distributions clearly. Where both colour shading and data figures are shown, as for net annual accumulation of snow and for mean annual temperatures, the effect is good, as one can see clearly the actual measurements and the degree of interpolation. However, the surface elevation and ice thickness maps show neither profile

* American Geographical Society. Antarctic Map Folio Series. Folio 1: *Aeronomical Maps for the Antarctic*. By R. Penndorf, T. M. Noel, G. F. Bourke, and M. A. Shea. Pp. 6+9 plates. (New York: American Geographical Society, 1964.) 3 dollars.

† Folio 2: *Physical Characteristics of the Antarctic Ice Sheet*. By C. R. Bentley, R. L. Cameron, C. Bull, K. Kojima and A. J. Gow. Pp. 10+10 plates. (New York: American Geographical Society, 1964.) 4 dollars.

lines nor points of observation, since the former are shown on a separate map. In theory one superimposes the maps on a light table as necessary—in practice a light table is not always available, and even if it is, the maps differ in placing in relation to the sheet edges, so that careful positioning is needed.

The maps give a reasonably full cover of material available in late 1963, but there are some omissions. Treatment of the Antarctic Peninsula by different compilers is inconsistent, since it is not always considered as part of the main ice sheet. Glaciological data from this region are both very variable and somewhat sparse, but ample information which is available on surface elevations has not been included. The text also states that meteorological observations have been obtained for one year or longer at twenty-one stations on the Antarctic Peninsula or off-lying islands, but the relevant map shows mean annual temperatures for only twelve of these stations. Reliable data for some of the missing stations are available from references given in the useful list of data sources which accompanies the text.

Another obvious omission is that the ice-thickness map does not show data from the French traverse of 1957–58 although the relevant reference is included with the text.

Studies of borehole data on temperatures, densities, crystal size and orientation, borehole closure and of stratigraphic profiles are shown diagrammatically on three data sheets. The introductory text is clear, and there is an excellent table setting out various over-snow traverses on the main continent, although the Antarctic Peninsula is again omitted.

For 7 dollars (3 dollars for Folio 1 and 4 dollars for Folio 2), the material supplied is good value and will provide a suitable reference source. Being in separate sheets, the maps can be revised and re-issued as necessary, and even in less than two years since they went to press, and under six months since their arrival in the United Kingdom, substantial additions to many of the maps could already be made. The intention in the United Kingdom and the U.S.S.R. to publish bound atlases at a definite time, rather than loose-sheet folios, has much to recommend it for convenience of librarians and general users. The maps are perhaps more important in supplying background information in fields related to a specialist's own studies, rather than to supply knowledge in his own field. Whatever the map, the specialist will almost always be aware of later data which are missing.

G. DE Q. ROBIN

OBSERVATIONS OF POLARIZED OH EMISSION

By DR. S. WEINREB, PROF. M. L. MEEKS and J. C. CARTER

Lincoln Laboratory, Massachusetts Institute of Technology, Lexington, Massachusetts

AND

PROF. A. H. BARRETT and A. E. E. ROGERS

Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, Massachusetts

IN a recent article Weaver, Williams, Dieter and Lum¹ reported strong microwave emission lines in the *HII* regions *W3*, *W49*, *W51*, *W75*, *NGC 6334* and *Orion A* at a frequency of approximately 1,665 Mc/s. In some cases the lines exhibited complex spectral structure, and in all cases the emission at 1,667 Mc/s bore little resemblance in intensity and/or structure to the 1,665 Mc/s emission. In particular, the emission in the region of *W3* was approximately 30° K at 1,665 Mc/s, while no emission was detected at 1,667 Mc/s. Weaver *et al.* concluded that the observations could not be entirely attributed to OH and postulated the existence of an unidentified microwave line which they called "mysterium".

In this article we wish to report observations of emission lines near the source *W3* which reveal that: (a) emission is present not only at 1,665 Mc/s but also at 1,667 Mc/s and 1,720 Mc/s with frequency spacings as predicted from the OH molecular spectrum²; (b) some of the emission at 1,665 Mc/s is linearly polarized by as much as 37 per cent; (c) the position of the maximum 1,665 Mc/s emission is displaced from *W3* by approximately 14 min of arc; (d) emission features as narrow as 1–1.5 kc/s have been observed. As yet we have not observed other regions. In our opinion, "mysterium" is anomalously excited OH.

The observations were conducted using the 120-ft. parabolic antenna of the Haystack Research Facility³ of Lincoln Laboratory, Massachusetts Institute of Technology, and a spectral-line autocorrelation radiometer. The radiometer is similar to that used in the initial discovery of the OH lines⁴; however, the present radiometer is an entirely new system with several improvements. A room-temperature parametric amplifier is incorporated in the radiometer, and a digital correlator allows the examination of the spectrum in band-widths which can be selected from 40 kc/s to 4 Mc/s. The frequency resolution is 1/40 of the band-width. A Univac 490 computer is

coupled directly to the radiometer output and produces the frequency spectrum immediately after the end of each pre-set integration time. The antenna beam-width is 23 min of arc and the overall system temperature is approximately 200° K. The measured continuum antenna temperatures were approximately 240° K on *Cassiopeia A* and approximately 12° K on *W3*.

Typical emission spectra at 1,665, 1,667 and 1,720 Mc/s are shown in Fig. 1 and the results of our observations are summarized in Table 1. Because of our ability to examine the spectra with a frequency resolution of 1 kc/s, more lines are reported in Table 1 than reported by Weaver *et al.* Most of our observations were also made at the position of maximum 1,665 Mc/s emission, $\alpha = 2^h 23^m 29^s$, $\delta = +61^\circ 38' 1''$ (1950.0), slightly displaced from *W3*. The region of strong emission at 1,665 Mc/s

Table 1. SUMMARY OF PRINCIPAL OH SPECTRAL FEATURES

Feature No.	Velocity (km/s)	Feature width (kc/s)*	Average antenna temp. (°K)	Polarization (per cent)	Position angle	Comments	
1,665 Mc/s, 1 kc/s resolution:							
1	-49.1	1.3 ± 0.3	6.1 ± 0.6	30 ± 12	145° ± 10°	Appears as two or more blended lines Line profile changes with feed position angle Line blended with adjacent lines	
2	-46.5	3.0 ± 0.4	14.3 ± 1.5	2 ± 6			
3	-45.2	3.0 ± 0.2	35.4 ± 3.0	37 ± 6	65° ± 4°		
4	-44.5	1.7 ± 0.3	7.0 ± 0.7	22 ± 16	107° ± 22°		
5	-43.7	1.6 ± 0.2	14.8 ± 1.5	22 ± 10	140° ± 16°	Spectrum not resolved due to poor signal-to-noise ratio	
6	-43.1	1.2 ± 0.4	3.1 ± 0.3	10 ± 10			
7	-41.7	1.6 ± 0.3	7.2 ± 0.7	16 ± 16			
1,667 Mc/s, 1 kc/s resolution:							
1	-45.5	3.0 ± 0.5	2.2 ± 0.3	10 ± 10			
2	-43.8	1.2 ± 0.5	1.3 ± 0.3				
3	-43.0	1.6 ± 0.5	1.7 ± 0.3				
1,720 Mc/s, 3 kc/s resolution:							
~ -44			0.85 ± 0.3				

* Feature widths given have instrumental width removed.

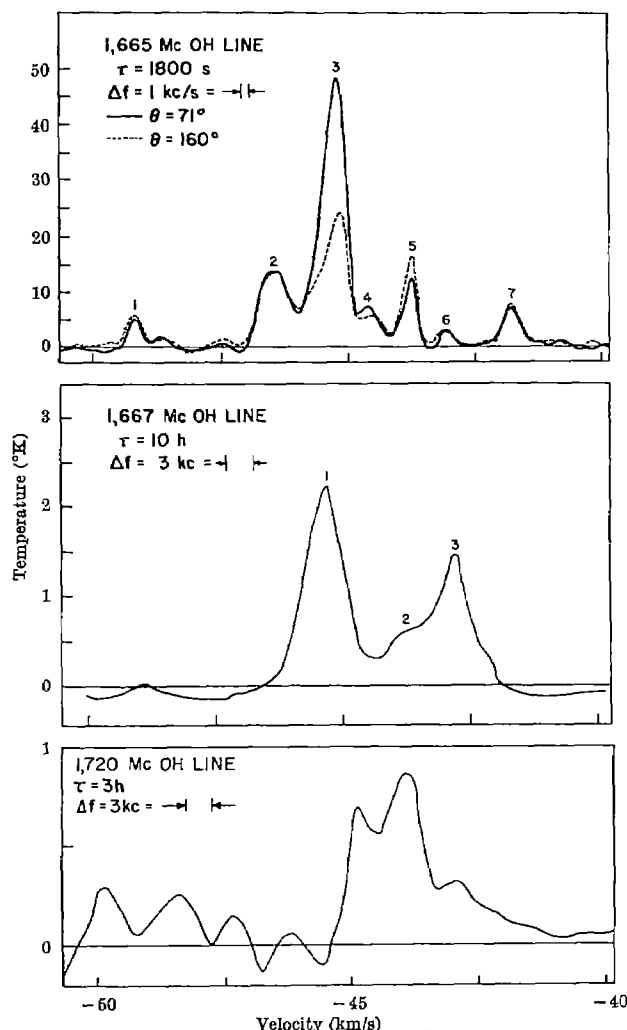

Fig. 1. Examples of OH-line spectra at 1,665, 1,667 and 1,720 Mc/s. The antenna temperatures are shown as a function of velocity relative to the local standard of rest. The data presented in Table 1 are, in some cases, of longer integration time and higher resolution than the examples presented in this figure.

appears to be of slightly greater angular extent than our beam-width, as adjudged by the intensity of the -45 km/s line. The values of Table 1 must be considered uncertain to the extent that blending of the lines occurs in some cases. Spectra with 1 kc/s resolution at various polarization angles reveal that some of the lines may be quite

complex and consist of two or more lines blended together. The observations also suggest that a small, but significant, amount of absorption may be present, particularly at 1,667 Mc/s, thereby making interpretation of the spectra difficult without further observations.

The observations clearly show that a large anomaly exists in the intensity ratios of the lines. For small optical depths, the intensities for the 1,665, 1,667 and 1,720 lines have theoretical ratios of 5:9:1 whereas our observations give approximately 50:2:1. The 1,612 Mc/s line was not detected during our limited search and its intensity appears to be less than the 1,720 Mc/s line. We observe a maximum antenna temperature of 50° K for the 1,665 Mc/s emission which implies, from considerations of antenna efficiency and beam filling, that the brightness temperature is in excess of 200° K. On the other hand, the narrowness of the lines implies maximum kinetic temperatures of 15° – 30° K. Therefore, the population distribution among the OH energy-levels must be established to a large degree by radiative processes and collisions are relatively ineffective.

The existence of strongly polarized OH emission is both surprising and difficult to explain. Possible polarization mechanisms are: (1) Zeeman effect; (2) Stark effect; (3) resonance scattering; (4) amplification, through a maser-type population inversion, of polarized background radiation. The approximate difference of 90° between the position angles of the -45.2 km/s line and the -43.7 and -49.1 km/s is characteristic of the Zeeman effect when viewed normal to the magnetic field. If the polarization is due to the Zeeman effect, magnetic fields of the order of 5×10^{-3} gauss are indicated. The Zeeman effect is unique among the four mechanisms listed above because it is the only mechanism which will give rise to circular polarization. Therefore, observations of this region with circular polarization are extremely important. Furthermore, if magnetic fields of the order of milligauss are present, 21-cm emission and absorption in the neighbourhood of W3 should be critically examined.

OH EMISSION IN THE DIRECTION OF RADIO SOURCE W49

By B. ZUCKERMAN, PROF. A. E. LILLEY and H. PENFIELD

Harvard College Observatory, Cambridge, Massachusetts

FOLLOWING the first detection of microwave lines of OH in emission near the source W49 by Gundermann¹ and by Goldstein and Gundermann² at Harvard University, similar emission was observed in a number of other galactic radio sources³. These initial investigations revealed a number of surprising results, particularly that the $F=(1 \rightarrow 1)$ 1,665 Mc/s transition has a greater intensity than the $F=(2 \rightarrow 2)$ 1,667 Mc/s transition, a reversal of the expected result.

In this article, we discuss recent detailed observations of OH emission in the direction of the source W49 and preliminary results for W51. We have obtained 3 kc/s resolution spectra of W49 at the OH frequencies of

1,665 Mc/s and 1,667 Mc/s with two radio telescopes: the Harvard University 60-ft. radio telescope and the 120-ft. Haystack telescope of the Lincoln Laboratory of the Massachusetts Institute of Technology⁴. These spectra have been quantitatively compared with each other. We have also obtained 1 kc/s resolution spectra at 1,665 and 1,667 Mc/s using the Haystack antenna. In view of the discovery of polarization of OH radiation in the source W3 by Weinreb, Meeks, Carter, Barrett and Rogers⁵, the W49 spectra have been checked for polarization and also for possible time variations. OH spectra in the region surrounding W49 have been obtained in an attempt to determine the angular size of the OH emitting

region and its position relative to the continuum source W49. Finally, using the results obtained on W49 and W51, we have carried out a preliminary investigation of the possibility that a spatial correlation exists between OH observed in emission and associated continuum sources.

The Harvard radio telescope is equipped with a cavity maser radiometer and a multi-channel filter bank composed of 10 units with available band-widths of 3, 25, 80 and 150 kc/s. At the OH frequencies, the antenna has a half-power beam-width of 52 min of arc and its aperture efficiency is 0.38. The mode of operation switches the radiometric system between the antenna input and a resistive comparative load maintained at approximately 4° K by immersion in liquid helium. The switching rate between the comparison load and the antenna is 3.5 c.p.s. An additive comparative noise source balances the system during operation. The total system noise is approximately 100° K. The characteristics of the Haystack OH spectral line system have been discussed by Weinreb *et al.*⁵

A quantitative comparison shows that the 3 kc/s resolution spectra for W49 obtained with the Harvard and the Haystack telescopes are practically identical in shape and differ only in amplitude. If an OH cloud and a continuum source are observed with two radio telescopes of different apertures, and if the cloud and source are small compared to the beam-widths of both telescopes, then the amplitude of each spectral feature should be proportional to the effective apertures of the telescopes. In this investigation, the ratio of effective apertures (Harvard/Haystack) is ≈ 0.38 . Using the total antenna temperatures at Harvard and at Haystack, we found that the observed ratios for the major spectral features at +17 km/s and +21 km/s (1,665 Mc/s transitions) are ~ 0.33 . If we take into account the known differences in effective filter shapes at Harvard and at Haystack, the observed ratio agrees quite well with the ratio of effective apertures.

We made a direct investigation of the angular size of the OH region responsible for the emission features at 1,665 and 1,667 Mc/s, by using 3 kc/s spectral resolution and the Haystack antenna. Comparison spectra were obtained for a number of positions close to W49. We were unable to detect any noticeable broadening of the Haystack beam, using the strong features at +17 and +21 km/s. Both the angular probe in position and the scaling of the spectral features imply that the region responsible for the OH emission is small with respect to the 23 min of arc beam-width of the Haystack antenna. The position of maximum OH emission lies at $\alpha = 19^h 7^m 55s$ and $\delta = 9^\circ 1'$ (1950.0).

Fig. 1 presents the spectrum of W49 obtained at the Haystack facility with a band-width resolution of 1 kc/s. The total integration time is 15 min. Numerous narrow spectral features are observed (~ 2 –3 kc/s at half maximum) and there is little correlation between the spectral shapes at 1,665 and 1,667 Mc/s.

The expected total line-width at half-power due to a thermally broadened cloud of OH is:

$$\Delta\nu \text{ (cycles/sec)} = 289\sqrt{T}$$

For the strongest features, the maxima observed in Fig. 1 are approaching the limit permitted by thermal broadening. However, since the OH emitting region is small in angular size, the apparent temperatures will continue to increase when observed by telescopes with larger effective areas and will exceed amplitudes $\sim 10^3$ °K. This argues for radiative excitation of the OH lines in the direction of W49, similar to the situation of W3 as reported by Weinreb *et al.*⁵. The continuum temperature which lies beneath the base-line in the two spectra in Fig. 1 is $T_c = 13^\circ \pm 1^\circ$ K.

In view of the polarization of the radiation from a similar source W3, as announced by Weinreb *et al.*⁵, we

have examined the 1,665 Mc/s peaks at radial velocities of +17 and +21 km/s with 3 kc/s and 1 kc/s band-width resolutions respectively for polarization effects. In each case, we made six measurements of the amplitude of the features, rotating the plane of polarization of the Haystack antenna feed system by approximately 30° between adjacent measurements. Using a definition of the percentage of polarization $p = 100 (T_1 - T_2)/(T_1 + T_2)$, where T_1 and T_2 are the maximum and minimum temperatures obtained with appropriate orthogonal positions of the antenna feed system, we conclude that the polarization of the features examined has an upper limit of 8 per cent.

We have examined our data for possible time variations in the +17 and +21 km/s features. There is nothing in the data to indicate that such an effect is present.

The prediction by Kardashev⁶ and the successful detection of several lines of excited hydrogen with transitions of the $n \rightarrow n-1$ type raise a question of possible confusion for OH spectral line research. Transitions of the $n \rightarrow n-1$ type occur throughout the region of the four OH lines when n takes on values between 155 and 160. However, calculations show that none of these hydrogen lines falls sufficiently close to the four OH lines to contaminate OH spectral analysis, and of the six lines that bracket the OH frequencies, none falls within 10 Mc/s of the OH lines.

The continuum source W49 has been studied by a number of workers. Bechis and Penfield⁷, utilizing the Haystack antenna at 8.25 Gc/s, have obtained a radio map of the region W49 clearly showing the two principal components of the source. Both components have angular widths of 3–4 min of arc and are separated by about 13 min of arc in right ascension. Data obtained at Green Bank⁸ at 750 Mc/s and at 1,400 Mc/s and at Haystack (8 Gc/s) suggest that one source is thermal and the other non-thermal (spectral index ≈ -0.6), their flux densities being equal at approximately 750 Mc/s. Weaver *et al.*⁹ noted that wherever OH had been found in emission (six sources) there was an HII region somewhere along the line of sight. If there is indeed an actual spatial correlation between continuum sources and OH emitting clouds, as our results on W49 and W51 suggest, then we can obtain a distance to the thermal component of W49 as well as to the clouds responsible for the OH spectra.

Akabane and Kerr⁹, utilizing the Parkes antenna, have attempted to deduce the distance to the source W49 by

Fig. 1. Spectra of W49 obtained with a resolution of 1 kc/s and an integration time of 15 min. The abscissae are frequency and velocity with respect to the local standard of rest. The ordinates are antenna temperature. The above spectra were obtained for the direction $\alpha = 19^h 7^m 55s$, $\delta = 9^\circ 0'$ (1950)

examining the absorption at 21 cm of its continuum radiation due to intervening HI. From their work, it appears that the non-thermal component, located some 10 min of arc away from the galactic plane, was essentially out of their beam as they observed the thermal source on the galactic equator. For a Sun-centre distance of 10 kpc, they arrive at a probable distance of 15 kpc and a possible alternative distance of 7.5 kpc.

Utilizing the standard differential theory of galactic rotation, we have inferred that the OH clouds are approximately either 14 kpc or 1 kpc distant from the Sun. If we assume that the OH clouds are physically close to the HII region, then this unambiguously places the OH clouds and the thermal component of W49 at about 14 ± 1 kpc. We found that the position of the greatest line amplitude of the major features at 1,665 Mc/s and 1,667 Mc/s was within ± 1 min of arc of the thermal component of W49 and unrelated to the non-thermal component. This argues in favour of a close physical association of the OH clouds and the thermal source. With a close physical association, the thermal region could be the radiative source responsible for the OH line excitation.

A further argument for associating the OH and continuum sources arises from our 8.25 Gc/s studies at Haystack of the source W51, which also appears to be complex, consisting of four components. Although we have not yet had an opportunity to examine this region in detail, we find, with Hoglund and Mezger¹⁰, that the source at α (1950) = 19h 21m 20s, δ (1950) = $14^\circ 23'$ (component A) is the strongest one at 8.25 Gc/s. We have noted OH emission at 1,665 Mc/s in W51, using 3 kc/s resolution at Haystack. We easily distinguished between the Westerhout position and the component A position, their separation being 17 min of arc. At the Westerhout position, we found an OH signal which, if real, was barely

above the noise, whereas at the position of component A we noted a number of emission features; the strongest was about 10° K.

Additional indication that a spatial correlation may exist between the OH in emission and continuum sources comes from a study of radial velocities in W51. The OH velocity was +58 km/s, whereas from a study of two newly discovered lines of excited hydrogen¹¹ in this source, we found ~ 60 km/s for a thermal source located in W51. The observed thermal region and the OH clouds appear to lie at the point of maximum radial velocity along the line of sight in their direction in III, bII, which suggests that their distance is about 6.5 kpc.

Wherever OH has been found in emission there appears to be an associated EII region. Therefore, it appears profitable to search for excited hydrogen lines in areas where OH is discovered in emission.

COMPARISON OF EXPERIMENTAL DATA OF THE EFFECTIVE ION MASS IN THE UPPER IONOSPHERE WITH A THEORETICAL STRUCTURE

By P. R. ARENDT

Institute for Exploratory Research, U.S. Army Electronics Command, Fort Monmouth, New Jersey

ELECTRON-DENSITY profiles obtained from evaluation of the readouts from the U.S.-Canadian topside-sounder satellite *Alouette* permit the measurement of the scale height in the upper ionosphere, from which information can be obtained¹⁻⁴ regarding the composition of the ionospheric regions. We centred our evaluation of the topside ionograms on the task of finding directly^{5,6} the exponential functions that govern the electron-density profiles. Thus, by the same process of numerical approximation, we obtain the electron density and the scale height. Therefore the computation reflects the main natural irregularities that are not smoothed out as by a differentiation of a density profile.

Our computation describes the electron density versus altitude profile in terms of an exponent α and the altitude h as follows:

$$N(h) = N_0 \exp(-(h-h_0)\alpha) \quad (1)$$

where N and N_0 are the electron densities at altitude h and h_0 respectively; the exponent α is a function of h . Under the assumptions mentioned below the exponent α can be considered the inverse electron-scale height $1/H$. Changes from region to region (of different but constant α) are made by our computation programme when the α for best data fit of a specific region has to be changed by more than the arbitrarily set 3 per cent. This setting results in an eventual uncertainty of the scale height by not more than 6-9 km within the altitude range we are going to consider.

Typical scale height versus altitude curves at daytime are given in Figs. 1-4. It is interesting to note a special fine-structure in the scale-height profiles. Very often data are presented in groups of constant exponent, thus reflecting a laminated structure (first observed by King¹). Each electron-density profile contains an inflexion point

Fig. 1. Scale height derived directly from topside ionograms

Fig. 2. Scale height derived directly from topside ionograms

Fig. 3. Scale height derived directly from topside ionograms

Fig. 4. Scale height derived directly from topside ionograms

where the curvature from the concave bending around f_oF_2 maximum changes to the convex curvature of exponential decay in the higher ionosphere. Obviously, a constant slope (that is, a constant exponent) will always be observed at the altitude of this inflexion. The altitude of inflexion is necessarily a function of the overall shape of the profile and might thus be related to seasonal, geographic, and other parameters. It appears to be rather pronounced at the magnetic equator¹. However, it is questionable whether a specific physical interpretation can be correlated to this inflexion point.

Our investigations⁶ of the altitude changes of typical plasma frequencies during magnetic activity have shown that the onset of a storm might be accompanied by a decrease in electron density. Such decreases may continue longer than the storm lasted as indicated by the local K index. It is plausible, therefore, that the slope of the scale-height profile is affected by magnetic events. The data shown in Fig. 1 (taken 2 h before a storm) and in Fig. 3 (taken 5 h after a storm) represent such magnetically disturbed conditions. A typical set of undisturbed data appears to be Fig. 4, which was taken more than a day after the last storm and more than ten days before the next storm. Comparison of Figs. 3 and 4 indicates that immediately after a storm the slope of the scale height is increased. During magnetically quiet periods (Fig. 4) the plateaux of constant exponent are repeated at nearly the same altitude during the passage of the satellite at the various points along its trajectory (36° – 51° N.). As indicated in Fig. 4 and Table 1, one can distinguish, during this passage for example, about five groups or plateaux, each of which is represented by a specific constant value. An average over the above latitude range taken during the same satellite passage results in five data pairs that can be considered representative for this latitude region at this specific time. Fig. 5 gives the end values from Table 1 in graphical form. The rectangles in Fig. 5 represent the spread of the single data. The lower three rectangles cover the entire range of the pertinent scale, indicating a really laminated structure that is less pronounced at higher altitudes partly because fewer data points are obtained there by our evaluation procedure. The combination of simultaneous data from various latitudes appears permissible in view of the fact

Table 1. AVERAGED SCALE HEIGHT

H , scale height; h , real height, both in km.

that the ionosphere above our region has been found very well stratified⁶ during magnetically quiet periods. The observed narrow spread of the data encourages the use of these data for a typical model (daytime, mid-latitude).

Considering the portions of the electron-density profile where constant exponents are observed, one might conclude that within such a range electrons and ions are each in specific isothermal equilibrium. In this case the inverse exponent is equivalent to the electron-scale height H :

$$\frac{1}{\alpha} = H = R(T_i + T_e)/Mg \quad (2)$$

Here R is the universal gas constant, T_i and T_e are the kinetic ion and electron temperatures, g is the acceleration of gravity and M is the effective ion mass (in atomic units); all parameters are a function of height; however, $T_i + T_e$ are considered constant for each region of constant $1/\alpha = H$. Since H and g are known, equation (2) reveals⁴ the ratio $(T_i + T_e)/M$ as a function of laminated altitude. The variation with altitude of equation (2) can be described by:

$$\frac{1}{M} \frac{dM}{dh} = \frac{1}{T_i + T_e} \frac{dT_i}{dh} - \frac{1}{H} \frac{dH}{dh} - \frac{1}{g} \frac{dg}{dh} \quad (3)$$

when it can be assumed that T_e is close to a constant value^{7,8} in the altitude range under consideration (300–1,000 km). The function $T_i(h)$ is not known exactly. Therefore, an empirical solution is suggested. A comparison of the possible magnitude of $\Delta M/M$ and $\Delta T_i/(T_i + T_e)$ as it can be obtained from the literature^{8,9} indicates that, for the altitude range in question, one might assume:

$$(1 \pm \epsilon) \frac{\Delta M}{M} = - \frac{\Delta T_i}{T_i + T_e} \quad (4)$$

where ϵ is a correction term which is also a function of altitude. The used numerical comparison of the terms in equation (4) is based on the neutral particle composition given by Harris and Priester⁹ for the mass data. This composition is not considered identical with the ion mass composition; however, the relative change in magnitude is assumed similar for neutrals and ions. A justification for equation (4) might be seen in the possibility that the lighter ions are more easily heated than the heavier ones by their interactions with the electrons. This effect will become more pronounced at higher altitudes.

Application of the empirical equation (4) permits a solution of (3) in case an assumption is made for the magnitude of $\epsilon(h)$. If we can assume $\epsilon = 0$ for the altitude interval in question we arrive at:

$$\left| \frac{dM}{dh} \right| = \frac{M}{2} \left\{ \frac{1}{H} \left| \frac{dH}{dh} \right| - \frac{1}{g} \left| \frac{dg}{dh} \right| \right\} \quad (5)$$

For $\epsilon \neq 0$ the above denominator reads $2 \pm \epsilon$ instead of 2.

Fig. 5. Averaged scale height during magnetically quiet period

Fig. 6. Effective ion mass versus real height. Lower curve, Harris and Priester data for neutral atmosphere; upper curve, data from Fig. 5 converted for isothermal equilibrium of electrons and ions. Dots: data from Fig. 5 converted for non-isothermal conditions as indicated by equation (5)

Equation (5) can be numerically solved, for example, by insertion of data from Table 1 provided, however, that a reasonable value is obtained for an initial reference point M, h . For this reference we have chosen rather arbitrarily the value of the altitude that Harris and Priester ascribe to $M = 16$ for daytime (11 h L.M.T.) under consideration. This value is 670 km, to which we co-ordinate the experimental value of $H = 245$ km from Fig. 5. With these assumptions we obtain the data points for M as shown in

Fig. 6. For comparison the original curve from Harris and Priester is also shown in Fig. 6 as well as another evaluation of our scale-height data which was based on the assumption that both T_i and T_e were constant. Obviously, both evaluations are not correct. The upper curve deviates apparently too much towards higher M values. The good correlation of the curve described by the row of points in Fig. 6 with the Harris and Priester curve cannot be taken as finite establishment of the applied correction term $\varepsilon = 0$. However, it is taken as an indication that an application of equation (5) comes closer to the true composition than the assumption of a completely isothermal medium (T_i and $T_e/T_i = \text{constant}$).

Bauer has informed me that he has referred to a more realistic reference point derived from rocket probes for the ionic mass 16, which point is related to an average altitude of 300 km, that is near the inflexion point of the profile. Thus the dotted curve in Fig. 6 has to be moved downwards to show a variation of M between 16 and 7 in the range 300–800 km.

DEPENDENCE OF THE PROPERTIES OF MOVING STRIATIONS IN THE PLASMA OF THE POSITIVE COLUMN ON SOME EXTERNAL AND INTERNAL PARAMETERS

By G. LAKATOS* and DR. J. BITÓ

Industrial Research Institute for Telecommunication Technique, Budapest

IN general, gas and vapour discharges occur associated with a number of oscillatory phenomena. Even under the simplest conditions, in the event of direct current discharges, a number of discharge anisotropies or instabilities in the state of equilibrium of the plasma can be demonstrated, which may lead to the generation of oscillations. Of these oscillations there is one which stands out because of its regularity. This is the so-called plasma oscillation which has been demonstrated and theoretically discussed by Langmuir and Tonks¹. These oscillations are characteristic of the given discharge plasmas; they accompany them all, and may be demonstrated in the positive column by means of a pair of Lecher-wires. Their frequency can be written:

$$n_e = \left(\frac{N_e \cdot e^2}{\pi m_e} \right)^{1/2} \quad (1)$$

where n_e is the frequency, N_e is the electron concentration, e the charge of electron, and m_e the electron mass.

The same relationship holds good for ions merely substituting the corresponding numerical values in the formula. For electron oscillations, using equation (1), a value of about 10^8 c/s is obtained for the frequency at an electron concentration of 10^{10} electrons/c.c. The frequency for ion oscillations, however, is much lower, due to the mass proportion and concentration assumed being smaller in certain instances.

In addition to these typical plasma oscillations (electron and ion oscillations), there is still another oscillation process

worth mentioning—a process which also regularly accompanies direct current discharges. This process is known as 'striation', and two specific forms of the process can be distinguished², namely the standing and moving striations.

As for the frequency, the study of striation does not require the rather complex techniques required for the so-called plasma oscillations, and for striations the frequency can be shown to be in the 10^2 – 10^4 -c/s range. Results published in the literature in this field have already been discussed by one of us in an earlier paper³.

A number of research workers are at present engaged on investigations of these striations, and are exploring their generation under various conditions. So far as the origins of the striations are concerned, no uniformly accepted theory has as yet been formulated. Certain research workers are investigating the processes occurring in the region of the electrodes for the anisotropy responsible for the phenomenon of striation—which can be demonstrated in the positive column and which is generally accompanied by variations in light. Others believe the origin of striation to be in the temporal changes of the basic processes of the positive column (excitation, diffusion, variation in the concentration of metastable atoms, recombination, ionization, etc.). Some are concerned with investigations of parameters influencing these striations^{2–4}, and by way of these studies are trying to draw conclusions as to their physical nature. Using the earlier findings of Szigeti⁵, one of us⁶ has succeeded in demonstrating the influences of certain internal plate-side parameters of the discharge tube on the moving striations within the positive column

* Now at the Research Institute for Electrical Industry.

of a low-pressure gas discharge. Studies are also being undertaken on influences external to the gas discharge tube which affect the moving striations. According to Yoshimoto *et al.*¹⁰ the velocity of the moving striations can be influenced by certain external conditions (ambient temperature, external resistance, etc.) in a critical manner. Pekarek¹¹ also mentions a weak influence of external circuits on the moving striations. Moreover, according to Nedospasov *et al.*¹², the external effects will, in addition to the velocity, influence the wave-length of the striations.

Donahue¹³ believes that for constant electrical and external parameters (temperature, geometry, etc.) the phenomenon of striation characteristic of direct current discharges can be considered as a superposition. In this case the moving striation is characterized by two space-charge waves moving in directions opposed to each other. In the discharge tube these space-charge waves move in conformity with the sign of the space-charge in opposing directions. Of these waves the negative space-charge wave composed mainly of electrons is characterized by a higher velocity.

The subject-matter of the tests to be described here was the investigation of the characteristic properties of these higher-speed space-charge waves at a variety of discharge currents. The instrumentation and set-up of the measurements performed during the tests were similar to those described by Donahue¹³. We have already described this set-up in an earlier paper, which deals with the pressure-dependence of the striation frequency and the speed of propagation³.

Striation in the direction of the axis of the positive column may be controlled by factors inside and outside the discharge in a number of ways^{3,4,5}. Thus, among other effects in the event of using Penning gas (that is, a gaseous mixture of mercury and argon), the process of striation is likely to be influenced by variations in the ambient temperature, through the variation of mercury-vapour pressure and the consequent variation of the concentration of the neutral atoms. It is a well-established fact that in the event of mercury vapour discharges the concentration of mercury atoms in the discharge is determined by the wall temperature of the discharge vessel through the partial pressure resulting from the saturated vapour pressure of the mercury.

Another object of the tests reported here was to study, using a Penning gas, the influence of certain external and internal parameters on the moving striations of the d.c. mercury vapour discharge, and to explain the dependence of the striations on these parameters. The following were included: as external parameters, the limiting resistance and ambient temperature; as internal parameters, the discharge curve.

No investigations of the external parameters of moving striations are known to us from the literature which have included studies of the dependence of temperature. Such tests would be justified by the aforementioned character of the mercury-vapour discharge in this type of d.c. discharge. For the theoretical description of the phenomenon of oscillation we accepted the calculations made by Kapzow¹⁵ for an equivalent circuitry, and followed the trend of thought of his calculations.

For purposes of measurement, we made use of the method introduced by Donahue¹³ and described by us in detail in an earlier paper³. Accordingly, in order to test the frequency of a moving striation, its nodes and light maxima, recourse was had to a method using photocells, and, by passing the signals of the photocell through an amplifier-stage, direct observations could be made on an oscilloscope screen. With the use of the oscilloscope the wave-length and frequency could be estimated (by means of Lissajoux curves). Furthermore, the light intensity of the striae formed during striation could be investigated along the discharge tube as a function of distance.

The discharge was supplied by a stabilized d.c. source while the discharge current was limited by symmetrically

arranged ohmic resistances in series. The discharge tube used on this occasion had a glass wall 1 mm thick; its length was 1,200 mm, and its outer diameter was 38 mm. After the appropriate vacuum treatment the tube was filled up with a mercury-argon gas mixture at a mercury column pressure of 3 mm, and about 60 mg mercury. To maintain the mercury vapour pressure at a constant value the discharge tube was placed in a water-jacket, and water was circulated continuously at a fixed rate. By using an ultra-thermostat, the temperature of the water responsible for temperature stabilization could be set at any value specified with an accuracy of $\pm 0.02^\circ \text{C}$. Tests began after a steady-state operating period of the discharge tube of 20 min, at specified predetermined stabilized temperatures of 20° , 25° and 40°C .

(a) *Influence of the external resistance on the moving striation.* When these tests were made the discharge tube was supplied from the stabilized d.c. source already mentioned, with an arc current of 100 m.amp, without specially heating the cathode. As an external limiting element during the first period of the tests a variable ohmic resistance was used which had negligible inductance. For the various values of the supply voltage (200, 300, 400 V) the external ohmic resistance was set so that during the tests the value of the current invariably remained 100 m.amp. By means of the measuring methods already described, and for a stabilized temperature of $25 \pm 0.02^\circ \text{C}$, the results shown in Fig. 1 were obtained. In Fig. 1 the dependence of the various characteristics on the value of the external ohmic resistance applied can be followed for an arc current of 100 m.amp. Curves are plotted for A , the amplitude of the light intensity variation, for v , the travelling speed of the moving striation, and for the resistance-dependence of the wave-length λ of the striation and the frequency ν . Of the two striation waves of different velocity detectable in the discharge, the parameters in the diagram in Fig. 1 apply to that travelling at the higher speed.

In the second set of tests, in addition to the ohmic resistance in series, an inductance coil, also in series, was used as an external influence. This resistance was alternately inserted or removed, as required. Its value was 1.5 henries, and the ohmic resistance was 10 ohms. With the inductance coil inserted in order to maintain the resultant ohmic resistance of the outer circuit on a constant value, the value of the original variable resistance had been reduced by 10 ohms. The effect of the inductance on the frequency of the moving striation for an arc current of 20 m.amp is shown in Table 1.

Table 1
Inductance coil
Inserted Removed
541 498

From Fig. 1 it can be seen that for an unchanged arc current the value of the external limiting ohmic resistance

Fig. 1. The various parameters of moving striations as functions of the value of the applied external ohmic resistance for an arc current of 100 m.amp. A , Amplitude of the variation of light intensity in arbit units; v , travelling speed of the moving striation in 10^8 cm sec $^{-1}$; λ , wave-length in cm; ν , frequency in 10^3 c/s units

Fig. 2. Current dependence of frequency n of the moving striation for various supply voltages, 200, 300, 400 V; I_t , discharge current

will, in the range under test, influence the amplitude of the light variations in the moving striation, the speed of propagation and the wave-length of the moving striation; however, it will not affect its frequency. The conclusion may thus be drawn that in the range in question the internal parameters of the discharge will have a decisive effect on the frequency of the moving striation.

On the other hand, what Table 1 shows is, provided that the required conditions exist, the presence of the inductive member of the external limiting element affects the frequency of the moving striation, that is, in this case it is not the internal parameters of the discharge alone that determine the frequency.

(b) *Influence of the shape of the voltage versus current plot on the moving striation.* In this set of tests, by increasing the range of current, measurements were carried out in the discharge current range between 5 and 200 m.amp.

In Fig. 2 curves have been plotted for the current-dependence of the frequency of the moving striation at a stabilized temperature of 25° C, first in the current range of 20–200 m.amp, and then of 5–20 m.amp. As may be observed, the shapes of the two frequency characteristics differed fundamentally from one another in the two ranges. In the 20–200 m.amp range the frequency of the moving striation could be controlled mainly by means of the internal parameters of the discharge, whereas in the 5–20 m.amp range together with the internal parameters the external parameters were having a remarkable influence on the character of the current-dependency of the frequency.

From the results plotted in Fig. 2, and using the results of measurements made at 20° and 40° C, an empirical formula was derived for the current-dependence of a frequency n in the range between 20 and 70 m.amp:

$$n = n_c(T) + C(T) \log i_t/i_{0t} \quad (2)$$

where $i_{0t} = 20$ m.amp, i_t denotes the discharge current, n_0 is the frequency of the moving striation at i_{0t} , T is the temperature of the thermostating water-jacket, and $C(T)$ is a constant at the given temperature.

It could be shown that with rising temperature T , the value of frequency n_0 tended to drop, while the value of C increased.

A further conclusion drawn from the results was that with increasing vapour pressure the frequency was decreasing in the range between 5 and 40 m.amp, whereas it was rising at currents of 120 and 130 m.amp. It should be noted, however, that the curve plotted in Fig. 2 has a rather marked kink at 120 m.amp. The conclusion to be drawn from these results is that the concentration of the mercury atoms, as one of the internal parameters, had a slight effect on the frequency response of the moving striation.

The experimental results established for the current dependence of the light and current oscillations of the moving striation are shown in Figs. 3 and 4. As was observed by Bauer²¹ using a supply voltage of 160 V, the light oscillations had a relative maximum when the voltage-current plot had a maximum. With this observation in mind we investigated the problem of the current dependence of the light oscillations, the results of which are plotted in Fig. 3. The amplitude of the light variation, L_o , was a maximum at 50 m.amp, and measurements showed that this maximum was independent of the value of the supply voltage—a circumstance which seems to indicate that the effect was independent of the external resistance. A dependence could, however, be shown below the discharge current of 20 m.amp and above 70 m.amp.

The curve of the amplitude of the current variations has been plotted in Fig. 4, and for a discharge current

Fig. 3. The amplitude L_o of the variation of light intensity as the function of the discharge current i_t for various supply voltages

Fig. 4. The amplitude L_o of the current variation as the function of the discharge current

Fig. 5. Stabilization for various supply voltages

of 120 m.amp this curve has a maximum at the kink in the curve in Fig. 2.

In Fig. 5 the voltage versus current characteristic has been plotted for the gas-discharge tube under test, with the known resistance 'straights' associated with working points P_1 and P_2 . At working point P_1 a steep curve section is associated with the lower current intensities. The angle closed by the resistance 'straight' and its associated characteristic section changes here much more markedly than, for example, in the neighbourhood of working point P_2 . Consequently, for a given current intensity variation, a much greater voltage variation will arise, for example along the resistance 'straight' associated with the 400-V supply than along the resistance 'straight' belonging to the 200-V supply. We believe that this stronger voltage variation offers an explanation of why the frequency, as shown in Fig. 2, becomes dependent on the external parameters of the tube exactly at a current intensity of 20 m.amp corresponding to the working point P_1 in Fig. 5. This problem will receive a theoretical examination according to the method established by Kapzow¹⁵ in the following section.

(c) *Influence of the ambient temperature on the moving striation: theoretical study of the influence of external parameters.* In Fig. 6 the discharge current I_d and the burning tube voltage V_t of the discharge tube have been plotted at a stabilized wall temperature of 25° C. It may be observed that for low current intensities the slope of the curve is extremely steep and of a negative character.

The dependence of the frequency of the moving striation on the discharge current is shown in Fig. 2 for a wall temperature stabilized at 25° C. Measurements were made in the current range 5–200 m.amp. The external limiting resistance used in the current range 5–20 m.amp had an effect on the frequency of the striation⁴. A sharp kink in the frequency curve manifesting itself at the discharge current value of 120 m.amp could be found at all three test temperatures, that is, 20°, 25° and 40° C, for the same current. The curve plotted for the current-dependence of the striation frequency followed the trend of the curve plotted in Fig. 2 for a temperature of 25° also at the other two temperatures tested.

In Fig. 7 the temperature-dependence of the frequency of the moving striation is shown for a few values of the discharge current. For currents below 120 m.amp the temperature-dependence curves have a tendency to decline; with rising wall temperatures the frequency of the striations tends to decrease. At 120 m.amp—the current at which the kink occurs in the curve plotted in Fig. 2—the temperature-dependence curve shown in Fig. 7 inverts, and for higher currents the frequency of the striation rises with rising wall temperature.

Fig. 6. Curve plotted for the discharge current, I_d , of the discharge tube versus the burning voltage, V_t .

Fig. 7. Temperature-dependence of the frequency of the moving striation for specific discharge current values

As has been made clear earlier in this article, maintenance of the wall temperature at a predetermined value amounts to maintaining the concentration of the mercury atoms (which play a decisive part in the discharge) at a predetermined level. The argon atoms, owing to their higher excitation and ionization potentials, are only moderately represented in the basic processes of the discharge still in a steady-state balanced condition compared with the mercury atoms.

The values for vapour pressure and the number of mercury atoms at the various test temperatures are shown in Table 2 (ref. 7). The well-known striking growth of concentration of the mercury atoms occurs in the temperature range between 25° and 40° C.

	20	25	40
Vapour pressure of the mercury atoms (10^{-3} mm Hg)	1.201	1.85	6.07
Concentration of mercury atoms (atom/c.c.)	3.95×10^{13}	5.94×10^{13}	20×10^{13}

Before discussing the results obtained here, certain characteristic sections in the current versus voltage curve in Fig. 6 deserve special attention. For small currents the curve has a negative directional tangent, whereas for currents larger than 20 m.amp the curve is first positive and later negative.

The characteristics of the curve shown in Fig. 2 for the current dependence of the striation frequency can perhaps be explained with the characteristic properties described earlier and the influence of the internal parameters of the discharge. In this connexion, we outlined our opinions at the second Czechoslovak Conference on Electronics and Vacuum Physics⁴, and pointed out that, whereas in the current range up to 20 m.amp the external parameters, mainly the value of the limiting resistance, affected the striation frequency in a decisive manner, for current above 20 m.amp it was mainly the internal parameters which determined the striation frequency. We also made it clear that for a theoretical description of the influence of the external factors the equivalent circuitry developed by Kapzow offered a convenient method¹⁵. A demonstration of this method follows later.

In all curves describing the current-dependence of the frequencies (Fig. 2) there is a break point at 120 m.amp for all three temperatures. At this point the frequency drops by 200–300 c/s, and then for currents in excess of 120 m.amp the curve progresses between values corresponding to the original frequency value and the break point, in a closely linear, monotonously rising manner up to 200 m.amp. The temperature-dependence of this frequency breakdown is represented in Fig. 7 by the curve marked with the 120-m.amp parameter.

The theoretical relationship for the influence of the ambient temperature according to Fig. 7 can only be established after further investigations. However, even without any further investigations the statement may be ventured that there may be a definite relationship between the variation of the concentration of neutral

Fig. 8 (a) Equivalent circuitry for the electric circuit of the discharge.
(b) Auxiliary figure for the notations used in the deduction

mercury atoms in accordance with Table 1 and the influence of the ambient temperature. A consequence of this relationship is perhaps the drop in the striation frequency with the growing mercury atom concentration below the current intensity of 120 m.amp.

From the fact that with the increase in concentration of mercury atoms the frequency variation curve becomes inverted at 120 m.amp, it can be concluded that owing to the larger energy losses associated with the larger current rate beyond 120 m.amp a change can occur in the heat dissipation conditions in the discharge. This may, among other things, influence the trend in the temperature-dependence of the moving striation frequency.

The influence of temperature should be considered as an external factor at the formation of moving striation. As has already been explained⁴⁻⁶, in specific sections of the current range the external parameters resistance, capacity and induction of the electric circuit have a critical influence. A method for studying this influence has been provided by Kapzow¹⁵. Assuming an equivalent circuitry for the discharge circuit, he discusses the conditions for oscillation by solving the second-order differential equation for the discharge circuit.

Accordingly, for the present investigations, the electric circuit for the discharge can be described by the equivalent circuitry as shown in Fig. 8a, where C denotes the sum total capacity of the discharge circuit and the water-jacket surrounding the tube which affects the discharge, R is the sum total resistance of the external circuit, L is the sum total induction given by these resistances and other circuit members, and E is the voltage of the d.c. current source maintaining the discharge.

By applying Kirchhoff's law in the vibrationless, balanced state of the discharge the following relation is obtained:

$$E = I \cdot R + U_0 \quad (3)$$

where U_0 denotes the tube voltage at a current I .

If with the start of an oscillatory process of any kind the current of the discharge changed to $I + i$, then corresponding to the discharge characteristic of a slope U' in accordance with Fig. 8b, the voltage drop of discharge would change to a value U_1 . Owing to the oscillations now in full swing a current i_1 would flow through condenser C , and also the current flowing in the equivalent chain RL would vary by a value i_2 .

Similar to equation (3), the following circuit relation can be written:

$$E = U_1 + R(I + i_2) + L \frac{di_2}{dt} \quad (4)$$

$$\text{since } U_1 = U_0 + \Delta U \quad (5)$$

$$\text{and } \Delta U = U' \cdot i \quad (6)$$

$$\text{further } U_1 - U_0 = \Delta U = \frac{1}{C} \int i_1 \cdot dt \quad (7)$$

$$\text{and then } CU' i = \int i_1 \cdot dt \quad (8)$$

$$C \cdot U' \frac{di}{dt} = i_1 \quad (9)$$

With this substituted in equation (4), since

$$i_2 = i + i_1 \quad (10)$$

the relations:

$$E = U_0 + U' i + R \cdot I + R \cdot i + R \cdot i_1 + L \frac{di}{dt} + L \frac{di_1}{dt} \quad (11)$$

and

$$E = U_0 + U' i + R \cdot I + R \cdot i + RCU' \frac{di}{dt} + L \frac{di}{dt} + LCU' \frac{d^2 i}{dt^2} \quad (12)$$

will be obtained. After turning the equations into their standard or a differential equation of the form:

$$LCU' \frac{d^2 i}{dt^2} + (RCU' + L) \frac{di}{dt} + (R + U') i + \underbrace{RI + U_0 - E}_{=0} = 0 \quad (13)$$

$$\frac{d^2 i}{dt^2} + \frac{RCU' + L}{LCU'} \frac{di}{dt} + \frac{R + U'}{LCU'} i = 0 \quad (14)$$

will be obtained. After solving this equation according to:

$$i = A_1 \exp(r_1 t) + A_2 \exp(-r_2 t) \quad (15)$$

where A_1 and A_2 are constants, the following equation may be written for r :

$$r = -\frac{1}{2} \frac{RCU' + L}{LCU'} \pm \sqrt{\frac{1}{4} \left(\frac{RCU' + L}{LCU'} \right)^2 - \frac{R + U'}{LCU'}} \quad (16)$$

or in a reduced form:

$$r = -\frac{1}{2} \left(\frac{R}{L} + \frac{1}{CU'} \right) \pm \sqrt{\frac{1}{4} \left[\frac{R}{L} + \frac{1}{CU'} \right]^2 - \frac{1}{LC} \left[\frac{R}{U'} + 1 \right]} \quad (17)$$

(a) If the quantity under the root sign is positive, then the current variation is of an aperiodic nature, and r_1 and r_2 are real. In this event the condition for stability may be written:

$$r_1 < 0 \quad (18)$$

$$r_2 < 0 \quad (19)$$

This condition can be satisfied, first, if

$$\frac{R}{L} + \frac{1}{CU'} > 0 \quad (20)$$

and, secondly, if the absolute value of the first term under the root sign is smaller than the square of the first term. Otherwise a positive r would also be possible, that is, to satisfy conditions (18) and (19) it is required that:

$$\frac{1}{4} \left(\frac{R}{L} + \frac{1}{CU'} \right)^2 - \frac{1}{LC} \left(\frac{R}{U'} + 1 \right) < \left[\frac{1}{2} \left(\frac{R}{L} + \frac{1}{CU'} \right) \right]^2 \quad (21)$$

that is, the inequality:

$$\frac{1}{LC} \left(\frac{R}{U'} + 1 \right) > 0 \quad (22)$$

exists, since both L and C are positive, for real r_1 and r_2 the condition for stability is given in the form:

$$\frac{R}{U'} + 1 > 0 \quad (23)$$

(b) If the quantity under the root sign in equation (17) is negative, then a solution will be found in the form:

$$i = A_1 \exp(-\delta t + j\omega t) + A_2 \exp(-\delta t - j\omega t) \quad (24)$$

where A_1 and A_2 are constants, and

$$\delta = \frac{1}{2} \frac{R}{L} + \frac{1}{CU'} \quad (25)$$

$$j\omega = \sqrt{\frac{1}{4} \left(\frac{R}{L} + \frac{1}{CU'} \right)^2 - \frac{1}{LC} \left(1 + \frac{R}{U'} \right)} \quad (26)$$

The condition for stability is that $\delta > 0$, that is, the expression in (25) must also be greater than zero. Thus the inequality:

$$\frac{1}{2} \left(\frac{R}{L} + \frac{1}{CU'} \right) > 0 \quad (27)$$

should exist. If conditions (22) and (26) exist at the same time, then the external parameters will cause no instability in the discharge.

By using relation (26) the oscillation frequency in the neighbourhood of the current value corresponding to the working point may be given which might then become the generator of the moving striation.

With the values of the external circuit elements in (26) and the slope of the curve associated with the current value in question inserted, a quantitative relation will be obtained showing that the frequencies of the oscillations are in fact within the range between 100 and 1,000 c/s.

In the course of the experiments reported here the ohmic resistance, capacity, and inductance of the external electric circuit were determined for the purpose of these calculations. The latter inductance is due to the inductivity of the ohmic resistance.

As an external value the capacity of the water-jacket surrounding the discharge tube had to be taken into

account. With this capacity taken up in the calculation the values of all other capacitive elements of the circuit become negligible. In Table 3 the circuit parameters associated with a 50-m.amp discharge current and the value of the slope U' taken from Fig. 6 have been compiled.

Table 3				
R	L	C circuit	C jacket	U'
3,440 ohms	12×10^{-3} henries	14×10^{-12} farads	2.1×10^{-8} farads	150 ohms

The value of the frequencies is markedly influenced by the values of U' and R , whereas L varies only slightly, and C may in this case be considered a constant (water-jacket). Depending on the slope and the character of the curve a variety of frequency values will be obtained from equation (26) for the various currents. As for order of magnitude, these frequency values agree with the experimentally established frequencies.

It is thus obvious that external parameters (especially temperature) together with the members of the external electric circuit have a critical influence on the striation processes. In the course of pertinent investigations more extensive and far-reaching information may be obtained concerning the fundamental physical phenomena occurring in the plasma.

KINETIC PARAMETERS FOR OXYGEN IN REACTIONS INVOLVING PURIFIED OXIDASES AND TISSUE SLICES

By DR. M. McCABE*

Department of Biochemistry, Institute of Diseases of the Chest, Brompton Hospital, Fulham Road, London

AND

DR. D. A. GILBERT

Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London

HAYAISHI¹ has recently summarized the apparent Michaelis constants for oxygen of several oxidase enzymes. In only one of the papers cited (that by Longmuir²) was the time-course of the reactions considered in any detail. In order to assess the suitability of Longmuir's polarographic apparatus to our own work, we have examined the applicability of both integrated and differential rate methods for determining the kinetic parameters for oxygen from the time-course of two oxidase reactions. These procedures are basically inferior to those in which only initial rates are considered due, for example, to effects resulting from the accumulation of products. However, we have found that consistent results are obtainable by these methods, provided excess catalase is added to decom-

pose rapidly hydrogen peroxide formed during the reactions considered. The good reproducibility of the values obtained for the parameters invites a more frequent use of these methods especially when the supply of enzyme is limited and maximum information must be gleaned from each individual experiment. Application of these methods to the results obtained on the oxygen uptake by intact cells (cf. Longmuir³, Chance⁴, Bander and Kiese⁵) leads us to propose an alternative interpretation of published results on the kinetics of tissue respiration.

The apparatus used for these investigations was essentially as described by Longmuir², the cell volume being approximately 18 ml. The experimental technique adopted was as follows: a buffered solution of the primary substrate (in large excess) was equilibrated with air (or oxygen at up to 3 atmospheres pressure) at 37°C, this

* Present address: Physical Biochemistry Department, John Curtin School of Medical Research, Australian National University, Canberra.

being followed by the addition of excess catalase (final concentration approx. 5 $\mu\text{g}/\text{ml}$). The latter had no effect on the diffusion current. The mixture was then introduced into the air-tight polarographic cells (maintained at the same temperature) and the reactions were initiated by the injection of 0.2 ml. of the appropriate enzyme solution. Glucose oxidase was obtained from Boehringer and Soehne, Mannheim, Germany. This enzyme is specific for β -D-glucose, but, since the preparation contained a highly active epimerase, the β -D-glucose concentration was effectively that of the total D-glucose present. Pig kidney D-amino-acid oxidase was purchased from Seravac Laboratories, Ltd., Colnbrook, England, the substrate used being D-alanine.

Analysis of the results obtained with both glucose oxidase and D-amino-acid oxidase shows that, under the conditions described, the reactions conform to simple Michaelis-Menten kinetics except at extreme values of oxygen concentration. Thus, if the data are plotted in the form of the integrated rate equation:

$$\frac{S_0 - S}{t} = V_m + \frac{K_m}{t} \cdot \ln \left(\frac{S_0}{S} \right)$$

(where S_0 and S are the oxygen tensions at time zero and time t respectively, V_m is the theoretical limiting rate and K_m the apparent Michaelis constant), the graphs obtained are linear over a considerable range of oxygen pressures (for example, 30–700 mm mercury). From the intercepts and slope it is thus possible to calculate both V_m and K_m . Alternatively, but perhaps less accurately, it proved possible to determine the rate of the reaction at any given partial pressure of oxygen from the slope of the time-course trace and hence obtain Lineweaver-Burk plots. The kinetic parameters can then be obtained in the usual way. In addition it is possible to determine the apparent reaction order for oxygen from the slope,

n , of the $\log \left(\frac{V_m - V}{V} \right)$ versus $\log S$ plot (where V is

the rate at the oxygen tension S). This value should be unity for simple Michaelis-Menten kinetics. By these methods the following range of values were obtained from the data of five experiments with each enzyme.

Glucose oxidase: $V_m = 240$ – $270 \mu\text{l. O}_2/\text{min}$ (mean 250); K_m (oxygen) = 120–190 mm mercury (mean 150); $n = 0.97$ – 1.05 (mean 1.00) (0.05 M phosphate buffer, pH 6, 0.01 M potassium chloride, 0.05 M glucose; initial oxygen tension varied from air saturated to 1 atmosphere).

D-Amino-acid oxidase: $V_m = 85$ – $95 \mu\text{l. O}_2/\text{min}$ (mean 89); K_m (oxygen) = 120–130 mm mercury (mean 125); $n = 0.94$ – 1.03 (mean 0.98) (0.05 M phosphate buffer, pH 8, 0.01 M potassium chloride, 5×10^{-2} M D-alanine; initial oxygen tension varied from air saturated to 3 atmospheres).

The K_m values in both cases (equivalent to about 170 μM for D-amino-acid oxidase and 210 μM for glucose oxidase) are in good agreement with the values obtained by other methods (140–300 μM and 200 μM respectively^{6,7}).

Non-conformation at both high and low oxygen tensions is to be expected as a result of the inapplicability of the simple theoretical equations at extreme values. In addition the degree of accuracy of the analytical methods is also lower in these regions. The deviations from simple Michaelis-Menten kinetics observed at very high oxygen tensions appear, however, to be real and could be due to inhibitions by oxygen or to intermediate intra-enzymatic reactions (that is, those not directly involving oxygen), or to the primary substrate being rate-limiting.

The calculations described were also applied to results obtained with actively respiring rat liver slices (using succinate as substrate) in place of the purified oxidase systems. Again the kinetics of the uptake of oxygen conformed to simple Michaelis-Menten kinetics over a wide range of oxygen tensions. Measurements of this

kind have been conducted by several workers²⁻⁴; each of these have referred to the apparent reaction order for oxygen as being anomalous, with a non-integral value in the region of 1.3–1.4. It should be pointed out, however, that these workers all used the *observed* maximal rate for the value of V_m . If, on the other hand, one uses the *theoretical* value for V_m (for example, the value obtained from extrapolation of the Lineweaver-Burk plots) as required by the relevant equations, a reaction order of unity is obtained (Fig. 1). It should be noted that the linearity of the Lineweaver-Burk plot implies a reaction order of unity irrespective of the nature or value of the maximum velocity. In the demonstration of the reaction order by means of the log-log plot, however, the interpretation will be dependent on the value used for the maximum velocity. Similarly, if the observed and theoretical limiting rates are significantly different, then large errors may be incurred in the estimation of the K_m value from the oxygen concentration at which the respiration is half-maximal. The anomaly can thus be resolved on the basis that the observed and theoretical maximum rates are not necessarily equivalent. On this interpretation, it would appear that, under the conditions used, the reactions directly involving oxygen are not initially rate-limiting but become so when the tension falls below the so-called critical value. Chance⁴ has described how the tissue respiratory data can be explained on the basis of sequential reactions involving four cytochrome components and this rationale is unaffected by our interpretation of the data.

In addition, we wish to mention that the apparent Michaelis constants for oxygen which we have obtained for tissue respiration (200 mm mercury, about 300 μM) differ by as much as one or even two orders of magnitude from those hitherto reported for the reaction of oxygen with rat liver cytochrome oxidase¹. It thus seems necessary to contemplate the existence of other rate-determining factors.

Some anomalies have already been considered by Longmuir and Bourke^{8,9}. Initially they felt the discrepancy might be explained by a gradient of partial pressure of oxygen through tissue down which oxygen diffused from the outside to the respiratory site within the tissue. However, this required a value for the diffusion coefficient for oxygen in tissue some hundred-fold less than through water. In addition, their original hypothesis did not explain the paradoxical result that the thickness of the slice appeared to have little effect on the parameter of critical oxygen tension of the tissue: the existence of a diffusion gradient would require that the critical oxygen

Fig. 1. Respiration of rat liver kinetic parameters for oxygen. A freshly prepared slice (0.4 mm thick) of rat liver was suspended in a medium (0.05 M phosphate buffer pH 7.4 0.05 M KCl 37° C) contained in a reaction cell of the Longmuir type. Respiration was initiated by injection of sodium succinate to a final concentration of 0.12 M. Curve A shows the conformation to simple Michaelis-Menten kinetics by means of the Lineweaver-Burk plot; this graph also indicates the method of determining the theoretical maximum rate (V_m , 73 $\mu\text{l}/\text{min}$) and the Michaelis constant (K_m , 220 mm mercury). The slope of the double logarithmic plot (curve B) gives the reaction order for oxygen (1.0).

tension should increase as the square of the slice thickness. Further examination of their experimental results led Longmuir and Bourke to the conclusion that diffusion could not be limiting, indeed the experimentally determined value of the diffusion coefficient for respiratory tissue appeared to be 10 times that for water. In addition, they considered that respiration of a slice might be limited by an oxidase with a low affinity for oxygen¹⁰.

The differences noted could arise from the existence of an active transport mechanism for oxygen within the cell. On the other hand, the results may merely reflect a marked dependence of the parameters on the conditions used, an alteration in the kinetic behaviour of the cytochrome oxidase as a result of cell disruption or perhaps the existence of different kinetic forms (isozymes) of the latter enzyme within a particular species.

We thank Dr. I. S. Longmuir for his advice and for use of facilities. One of us (D. A. G.) was supported by grants

URINARY METABOLITES IN THE ω -OXIDATION OF 2,4-DIMETHYLHEPTANOIC ACID

By DR. S. R. TANNENBAUM and PROF. S. A. MILLER

Department of Nutrition and Food Science, Massachusetts Institute of Technology, Cambridge, Massachusetts

WHILE examining the metabolism of 2,4-dimethylheptanoic acid-2-methyl-¹⁴C (DMHA) in the intact rat, it was found that approximately 20 per cent of the radioactive label was recoverable in the urine after 48 h, while more than 60 per cent was recoverable in respiratory carbon dioxide. (Manuscript in preparation. Normally, less than 1 per cent of the radioactivity from a carbon-14 labelled fatty acid is excreted in the urine.) An investigation of the nature of this radioactive material indicates that it may be the ω -oxidation product of the parent compound.

ω -Oxidation of fatty acids occurs when oxidation from the carboxyl end of the molecule is blocked, or when the acid is of medium chain-length^{1,2}. Tryding and Westoo examined a series of ¹⁴C-carboxyl labelled, methyl-substituted stearic acids³ which indicate that α -substitution has little overall effect on metabolism, while β - or α,α -disubstitution almost completely block β -oxidation. The demonstration of ω -oxidation *in vitro* in a cell-free system has also been reported⁴. On the other hand, there is no previous report concerning the metabolism of methyl-substituted fatty acids such as DMHA in which the substitution occurs on the α and γ carbon atoms.

Rats weighing 200 g were given a diet containing 10 per cent corn oil, and 0.2 per cent of DMHA-2-methyl-¹⁴C, specific activity 5×10^4 d.p.m./mg. The synthesis of the non-radioactive compound has been previously reported⁵. The radioactive label was incorporated through a minor variation of the published procedure which involved the condensation of diethyl 2-methylpentylmalonate⁶ with methyl-¹⁴C-iodide. The rats were housed in glass metabolism cages and urine was collected over a period of 48 h. The urine was acidified to pH 1, and continuously extracted with ether for 18 h with and without prior saponification with potassium hydroxide. Under these conditions, 93 per cent of the urine radioactivity (by liquid scintillation counting) could be recovered from the saponified urine, while only 57 per cent could be recovered from the unsaponified urine, indicating the presence of conjugated material.

Acids in the ether extract from the saponified urine were esterified with diazomethane⁶ and gas-chromatographed on a 2-meter column of 10 per cent diethyleneglycol succinate on acid-washed diatomaceous earth at a helium flow rate

Table 1. GAS CHROMATOGRAPHY OF ESTERIFIED ACIDIC COMPONENTS OF URINE OF RATS FED 2,4-DIMETHYLHEPTANOIC ACID

Peak	Retention time (min)*	Percentage of total urine radioactivity
A	76	21.8
B	70	35.5
C	56	7.4
Dimethyl succinate	16	2.3
Methyl 2,4-dimethylheptanoate	8.5	0

* A 2-meter column of 10 per cent diethyleneglycol succinate on acid-washed diatomaceous earth. Column temperature 100° C. Helium flow rate 60 ml./min.

of 50 ml./min. The chromatographic effluent corresponding to each major peak in the chromatogram was collected in glass capillaries immersed directly in liquid scintillation counting vials containing the scintillation liquid. Only three major peaks were found which did not correspond to a chromatogram of the urine of rats which had been fed the same diet without DMHA. These peaks were designated as shown in Table 1. None of these peaks had the same retention time as the methyl esters of a series of known compounds. (Methyl esters of: C-2, C-3, C-4, C-6, C-7, C-10 straight-chain dicarboxylic acids; methylmalonic, methylsuccinic, 2-methylglutaric, 3-hydroxybutyric, lactic, malic and citric acids. Ketoacids and fumaric acid are excluded, since they are not satisfactorily esterified and give non-volatile products with diazomethane.) The only compound which occurred in normal urine, and had a significant fraction of radioactivity, was dimethyl succinate (Table 1). No unmetabolized DMHA could be detected, although the method is suitable for identification of 5 μ g of this compound.

The materials corresponding to peak A, B, and C were trapped from the chromatograph in 1-ml. conical centrifuge tubes cooled with liquid nitrogen. Their infra-red spectra were determined in a Beckman IR-5 spectrophotometer using 0.05-mm cavity cells and a $5 \times$ KBr beam condenser. The spectra of peaks A and B were essentially identical both as pure liquids and in CCl₄ solution. This supports an assumption that they are diastereoisomers, as had previously been demonstrated for the parent compound, DMHA⁵. The spectra of A and B indicated that these compounds were esters. The transmission ratio of the carbonyl band at 5.75 μ to that of the C—H band at 3.75 μ was similar to that found in a series of dicarboxylic rather than monocarboxylic esters, suggesting that A and B

might be dicarboxylic esters. The presence of a band at 7.25μ also indicated the possibility of methyl groups on the chain⁷, particularly because the retention time did not correspond to that of a straight-chain compound. Although the specific activities of *A* and *B* could not be accurately determined owing to the very small amount of material available, on a volumetric basis, they appear to be in the range of 90 per cent of that of the parent compound, DMHA. It was tentatively assumed, therefore, that *A* and *B* were derived from DMHA via ω -oxidation and had the structure of 2,4-dimethylpimelic acid (1).

The mass spectrum of *B* was obtained with a CEC 21-130 mass spectrometer, and indicated fragment peaks typical of dicarboxylic esters^{8,9}. The peak at highest mass to charge ratio obtained was at *m/e* 185, and no discernible peak could be seen at *m/e* 216 where the parent mass ion (*M*) might be expected. It would not be unusual to find no parent mass ion for this type of compound, and the peak at *m/e* 185 probably corresponds to loss of a methoxyl ion (*M*-31). The base peak in the spectrum was at *m/e* 55 (C_4H_7), and corresponds to the branched paraffinic ion expected from the fragmentation pattern of (1). Other important peaks were found at *m/e* 88 (re-arrangement typical of 2-methyl substituted methyl esters (ref. 9)), *m/e* 59 (CO_2CH_3), and *m/e* 83 (C_4H_{11} , fragmentation at 1,2 and 5,6 with loss of H). No major peaks were detected that would not logically arise from (1). It is therefore tentatively concluded that (1) is the correct structure for *A* and *B*.

The infra-red spectrum of peak *C* was similar to that of DMHA, both in the position and intensity of the bands over the region of 3.3 – 9.5μ . The major differences in the spectra of *C* and DMHA are the presence in the spectrum of *C* of a strong band at 2.9μ and a medium intensity band at 10.6μ . The 2.9μ band is due to a hydroxy group and varies in position with dilution, as expected¹⁰, shifting to lower wave-lengths in more dilute solutions. The 10.6μ

band may indicate the type of substitution of the carbon bonded to the hydroxyl, but is of limited value¹⁰. Since only a trace of this compound was available, it was not possible to obtain any further information regarding its structure. On the basis of biological considerations, *C* might be the β -hydroxy derivative of DMHA, a compound which would be a normal intermediate of β -oxidation. Another possibility is that *C* is the ω -hydroxy derivative of DMHA, since it has recently been shown that the ω -hydroxy acid is an intermediate in ω -oxidation⁴.

It might have been expected *a priori* that fatty acids with alternate α -methyl substitution would be metabolized *in vivo*, via β -oxidation, with the same ease that has been demonstrated for fatty acids with a single methyl group in the 2 or 4 position³. Although 60 per cent of the ingested DMHA was oxidized to carbon dioxide via β -oxidation, the presence of 20 per cent of the radioactivity in urine might indicate that the alternate methyl groups along the chain present increased steric hindrance at one of the active sites in the β -oxidation enzyme system. Alternatively, it is possible that the extent of ω -oxidation is primarily a function of the chain-length of the compound—a hypothesis which remains to be tested.

'PINK SPOT' IN THE URINE OF SCHIZOPHRENICS

By R. E. BOURDILLON, PROF. C. A. CLARKE, A. PAULINE RIDGES and PROF. P. M. SHEPPARD, F.R.S.

Nuffield Unit of Medical Genetics, Department of Medicine, University of Liverpool

DR. P. HARPER*

Department of Psychological Medicine, University of Liverpool

AND

DR. SHIRLEY A. LESLIE

Psychiatric Registrar, Royal Liverpool Children's Hospital, Liverpool

SINCE Friedhoff and van Winkle¹ reported that they had isolated the compound 3,4-dimethoxyphenylethylamine (DMPE)—the 'pink spot'—from the urine of 15 out of 19 schizophrenics whereas they found it was absent in 14 mentally normal people, other workers have carried out similar investigations. Of these, Sen and McGeer², Kuehl *et al.*³ and Horwitt⁴ were confirmatory, Perry *et al.*⁵ and Faurbye and Pind⁶ were not, and Takesada *et al.*⁷ found that the compound was also present in nearly half their controls. In all these series the number of individuals tested was small, and moreover it appears that in none of them were the tests done in ignorance of the diagnosis. In the past many metabolic abnormalities have been described in schizophrenia,

but none has since been shown to have any fundamental bearing on the disease. It therefore seemed important to us to investigate the pink spot further, for if it could be shown to be causally related to schizophrenia this would provide important evidence favouring the abnormal methylation hypothesis as put forward by Osmond and Smythies⁸ and Harley-Mason⁹.

We have tested for the pink spot in the urine of 808 individuals to try to find out how often it is found: (a) in the different forms of schizophrenia; (b) in different types of mental disease; (c) in close relatives of schizophrenics; (d) in mentally normal people. To try to answer these problems, four experiments were planned:

Exps. I and II: Here two independent and 'blind' surveys were carried out in which separate workers ascertained the incidence of the pink spot using different

* Present address: c/o Research Facility, Rockland State Hospital, Orangeburg, New York.

methods for its detection and also different criteria for the assessment of schizophrenia.

Exp. III: A small series of family studies in which the close relatives of pink spot positive schizophrenic *propositi* were investigated.

Exp. IV: A survey of mentally normal individuals some of whom were apparently healthy in every way and some of whom were in-patients in the wards of two general hospitals.

Exp. I. The urines of 101 mental hospital in-patients, all 'possible schizophrenics', were tested with the primary object of finding the incidence of pink spot in the disease. The patients, who were drawn from three mental hospitals, consisted of acute and chronic cases and some had been off drug therapy for up to two months. All had at one time been given a provisional diagnosis of schizophrenia, and this and the drug therapy were known to the investigator (R. E. B.) who was testing for the pink spot. After he had assessed the presence or absence of this, each patient was interviewed and re-assessed by a psychiatrist (S. A. L.) who was ignorant of the pink spot finding. It was she who made the final assessment, and in about 17 per cent of the patients she thought the original diagnosis of schizophrenia was substantially in doubt; when this was so they were classed as non-schizophrenic. Where the diagnosis of schizophrenia was definitely upheld the patients were grouped into those who at any time had exhibited one or more of Schneider's first-rank symptoms¹⁰ and those who had not (these are referred to as Schneider positive and Schneider negative respectively). Afterwards the patients were also sub-divided into classical schizophrenics and those who showed only paranoid features without formal thought disorder or flattening of affect. The former for convenience are referred to as 'non-paranoid' and the latter as 'paranoid'. In five patients the information necessary for diagnosis was unobtainable either because the patients were unco-operative or because of language difficulties, and these five are classed as 'impossible to assess'.

The urine sample was, whenever possible, collected over 20 h, though in some cases shorter periods of collection proved more practicable. The extraction and the paper chromatography were carried out as described by Friedhoff and van Winkle¹ and this is referred to here as Method 1. Where there was marked interference by drugs the presence or absence of the pink spot sometimes had to be classed as 'impossible to assess'.

Because a much more detailed investigation would be necessary to ascertain that 3,4-DMPE was in fact being demonstrated we have, throughout this article, preferred to use the term 'pink spot' rather than 'presence of DMPE' in reporting the results.

These are given in Table 1 and the statistical analysis in Table 2. This consists of various comparisons using the χ^2 test or Fisher's two-tailed test for exact probability, whichever seemed the more appropriate. The control group were 149 mentally normal individuals (tested by Method 1) none of whom had the pink spot. Given also (Table 3) are the percentages of individuals with the pink spot within sub-classes.

Table 1. EXPERIMENT I
(a) Pink spot in relation to Schneider's first-rank symptoms

Schneider rating	Pink spot rating			Totals
	Positive	Negative	Impossible to assess	
Positive	35	11	6	52
Negative	7	16	4	27
Impossible to assess	4	0	1	5
Non-schizophrenic	0	16	1	17
Totals	46	43	12	101

(b) Pink spot in relation to non-paranoid and paranoid classification

Psychiatric assessment	Pink spot rating			Totals
	Positive	Negative	Impossible to assess	
Schneider positive { Non-paranoid	35	7	4	42
Paranoid	0	4	4	4
Schneider negative { Non-paranoid	5	5	10	20
Paranoid	2	11	13	26
Totals	42	27	69	138

Table 2. EXPERIMENT I. COMPARISON OF INCIDENCE OF PINK SPOT BETWEEN CLASSES

Comparison	χ^2	d.f.	Probability
Schneider positive with Schneider negative	11.57	1	<0.001
Schneider positive with non-schizophrenic	24.95	1	<0.001
Schneider positive with control			= 2.5×10^{-49}
Schneider negative with non-schizophrenic			= 0.029
Schneider negative with control			= 3.1×10^{-7}
Non-paranoid with paranoid	20.18	1	<0.001
Non-paranoid with non-schizophrenic	26.80	1	<0.001
Non-paranoid with control			= 8.06×10^{-32}
Paranoid with non-schizophrenic			N.S.
Paranoid with control			= 0.0099
Schneider positive with Schneider negative within non-paranoid			= 0.0388
Schneider positive with Schneider negative within paranoid			N.S.
Paranoid with non-paranoid within Schneider positive			= 0.0020
Paranoid with non-paranoid within Schneider negative			N.S.

Table 3. EXPERIMENT I. PERCENTAGE OF INDIVIDUALS WITH PINK SPOT WITHIN SUB-CLASSES

Sub-class	Percentage with pink spot
Schneider positive, non-paranoid	83.3 \pm 5.75
Schneider positive, paranoid	0.0
Schneider negative, non-paranoid	50 \pm 15.8
Schneider negative, paranoid	15.4 \pm 10.0

Exp. II. In the second experiment a different psychiatrist (P. H.) and biochemist (A. P. R.) worked together. The urines of 296 psychiatric in-patients drawn from two hospitals were investigated for the pink spot. The patients had often been in hospital for many years and included a larger proportion of chronic cases than in the first experiment. The samples of urine were analysed in ignorance both of the diagnosis and of the nature and quantity of drugs being received, so that a different part of the work was 'blind' from that in Exp. I. The psychiatrist selected the patients so as to include a variety of mental diseases, and he accepted the diagnosis given in the case-sheets and did not interview the patients personally as did the psychiatrist in Exp. I. He divided the cases into four groups: (a) 'non-paranoid' schizophrenics; (b) 'paranoid' schizophrenics; (c) schizophreniform syndromes (where although some features of schizophrenia were present it was uncertain whether or not the primary diagnosis was schizophrenia); (d) non-schizophrenics, which included such conditions as manic depressive psychosis, organic dementia and mental defect.

Since a different psychiatrist was scoring the cases and the diagnosis was assessed from the case sheets, the classes are probably not strictly comparable with those of Exp. I.

The chromatographic procedures were the same as those described by Friedhoff and van Winkle¹ (our 'Method 1'), but a different extraction procedure was used and the technique is referred to by us as 'Method 2'. A volume of 300–500 ml. of a 16-h overnight sample of urine was adjusted to pH 9.0 with 2 N sodium hydroxide. This was extracted three times with 100-ml. portions of 1,2-dichloroethane and the extracts dried over anhydrous sodium sulphate. The first extract was examined by ultra-violet absorption at 279 m μ . A peak at this value is a useful indicator of DMPE in the absence of interfering substances such as drug metabolites. The ultra-violet absorption spectrum helps particularly to distinguish DMPE from any closely related compounds which could not satisfactorily be resolved from it by the chromatographic procedures used. The three extracts were then combined and evaporated to dryness on a rotary evaporator. The residue was

Table 4. EXPERIMENT II. PINK SPOT ASSESSMENT IN 296 PSYCHIATRIC PATIENTS

Psychiatric assessment	Pink spot rating			Totals
	Present	Absent	Impossible to assess	
Non-paranoid schizophrenics	20	30	19	69
Paranoid schizophrenics	2	54	6	62
'Schizophreniform syndromes'	5	58	25	88
Non-schizophrenics	1	68	8	77
Totals	28	210	58	296

Table 5. EXPERIMENT II COMPARISON OF INCIDENCE OF PINK SPOT BETWEEN CLASSES

Comparison	χ^2	d.f.	Probability
Non-paranoid with paranoid	19.16	1	< 0.001
Non-paranoid with non-schizophrenic	27.05	1	< 0.001
Non-paranoid with control			$= 2.81 \times 10^{-18}$
Paranoid with non-schizophrenic			N.S.
Paranoid with control			N.S.

redissolved in dichloroethane for application to the chromatography paper. Authentic 3,4-dimethoxyphenylethylamine (K and K Laboratories) and mixed spots of urine extracts and authentic DMPE were applied alongside the urine extracts on the chromatography papers and the separation carried out.

The results of Exp. II are given in Table 4 and the statistical analysis in Table 5. The controls are 310 mentally normal individuals (tested by Method 2) one of whom had the pink spot. The results for the schizophreniform syndrome class have not been analysed because the group was probably very heterogeneous.

Exp. III. The pink spot was investigated in 20 close relatives of three schizophrenic propositi, all three of whom were found (by one or both of the two methods) to excrete the pink spot. None of the relatives was schizophrenic though some were reported as having other mental abnormalities.

The pink spot was not found in the urine of any of the close relatives, and these therefore are not significantly different from the control group of mentally normal individuals.

Exp. IV: Investigation of mentally normal individuals. These consisted of two groups. The first was made up of 265 healthy individuals, mostly undergraduates or university staff. The second was composed of 126 mentally normal in-patients, comprising 54 pre-operative and 20 post-operative cases, 10 patients with liver disease, 20 with chronic neurological states and 22 with general medical conditions. The pink spot was assessed by one or both of the two methods previously described and the series has acted as the control for the various comparisons.

All the controls were negative for the pink spot with the exception of one healthy individual, a woman aged 54. She suffered from migraine but was mentally normal and so was her family.

Comparison between Method 1 (Friedhoff and van Winkle) and Method 2 (ultra-violet + chromatography) in the investigation of the pink spot. In 133 people both methods for assessing the pink spot were used (Table 6).

Table 6 COMPARISON OF METHOD 1 AND METHOD 2 IN INVESTIGATION OF THE PINK SPOT

Friedhoff and van Winkle (Method 1)	Ultra-violet + chrom. (Method II)		Totals
	Pink spot positive	Pink spot negative	
Pink spot positive	12	7	19
Pink spot negative	2	112	114
Totals	14	119	133

Though there is a significant correlation, $P = 1.06 \times 10^{-10}$, between the results given by the two methods, there are discrepancies.

There are several reasons which might account for this non-concordance: (1) Method 2 may be less sensitive in detecting the pink spot (as opposed to DMPE); (2) slightly different substances may be being estimated; (3) one method may be more likely to produce undetectable false readings because of the presence of drugs; (4) there may be observer discrepancies. These possibilities are being investigated and will be the subject of a further article.

The association previously found between the pink spot and schizophrenia has been confirmed using large numbers. The results of Exp. I give compelling evidence that its presence is particularly associated with Schneider-positive individuals. It is much rarer in those who are Schneider negative and rarer still (if present at all) in non-schizophrenics.

In Exp. I the same patients have also been classified as to whether or not they only have paranoid features. The presence of the pink spot is particularly associated with the non-paranoid group but is significantly higher among the paranoid group than among the mentally normal controls.

When the individuals are classified as being Schneider positive and non-paranoid this sub-class has a significantly higher incidence of the pink spot than does any other group (83.3 ± 5.75 per cent). Thus to predict the presence of the pink spot the double classification is the most efficient.

Five individuals were so seriously disturbed that they could not be interviewed or assessed on the Schneider rating. The fact that four of them showed the pink spot suggests that these were true Schneider-positive non-paranoid cases as judged by our other results.

The second experiment using a different method for detecting the pink spot again shows the very strong association between the presence of the pink spot and 'non-paranoid' schizophrenia. The lower frequency of the pink spot may be due to any of the four reasons mentioned above and/or to the cases being less florid than in Exp. I. However, not enough have been scored by the Schneider rating to show whether the association is particularly with the Schneider-positive 'non-paranoid' group although the data show a strong tendency in this direction.

The evidence from the two experiments suggests that the pink spot is highly associated with schizophrenia and is not often present in other forms of mental disorder or in close relatives or in controls. Moreover, from our survey it seems highly improbable that diet and institution life play any part in producing the pink spot. An important problem is whether the abnormal metabolite precedes or is a result of the disease. The family data point to the latter conclusion, but it is possible that the pink spot only appears shortly before the disorder manifests itself, and that more refined techniques might demonstrate it in sibs. It would be interesting to follow pink-spot-positive patients with florid schizophrenia during remissions since these data might indicate whether the acuteness of the disease was associated with the quantity of pink spot material. If it did, this might explain its absence in sibs. The possibility has to be considered that drugs might be the cause of the pink spot. This is refuted by our data. Thus the relationship between schizophrenia and pink spot is at least as marked in those who had been off drugs for two weeks or more as in those who had not. Moreover, the non-schizophrenics on drugs showed no elevation of the frequency of the pink spot over those not on drugs. However, a complicating factor in using the pink spot for diagnosis is that drugs interfere both with the chromatography and with the ultra-violet absorption and it is difficult to obtain patients (particularly acute cases) who are not on drug therapy.

We thank Dr. B. Finkleman, Prof. F. J. Fish, Dr. A. V. de P. Kelly, Dr. I. Leveson, and Dr. B. Ward for allowing us to examine and test their patients, and the staffs of the hospitals concerned for help in the collection of samples. We also thank the Hon. Miriam Rothschild for obtaining the co-operation of certain of the individuals investigated.

INTERFERON APPEARANCE STIMULATED BY ENDOTOXIN, BACTERIA, OR VIRUSES IN MICE PRE-TREATED WITH *Escherichia coli* ENDOTOXIN OR INFECTED WITH *Mycobacterium tuberculosis*

By PROF. JULIUS S. YOUNGNER and PROF. WARREN R. STINEBRING

Department of Microbiology, School of Medicine, University of Pittsburgh, Pittsburgh

WHEN mice are injected intravenously with bacteria or bacterial endotoxin an inhibitor indistinguishable from virus-induced interferon appears in the circulation¹. *Salmonella typhimurium*, *Serratia marcescens*, and endotoxin from *Escherichia coli* produce peak-levels of circulating interferon at about 2 h after injection. Maximum interferon-levels following injection of *Brucella abortus* or Newcastle disease virus (NDV) are reached at about 12 h. To elucidate the mechanisms of the different time patterns of appearance of interferon, experimental procedures known to alter the reactivity of animals to the lethal or pyrogenic effects of endotoxin were investigated. Repeated exposure to endotoxin reduces the responsiveness of animals to subsequent injection of endotoxin, while prior infection with *Mycobacterium tuberculosis* is known to increase the reactivity of the host to endotoxin. These phenomena have been termed 'tolerance' and 'hyper-reactivity' in the literature dealing with endotoxin². In connexion with the investigations reported here, which primarily deal with interferon production rather than lethality or pyrogenicity, it seems more appropriate to use the term 'hyporeactivity' in place of 'tolerance'. This article deals with the modification of interferon appearance in the circulation which results from prior treatment of mice with endotoxin or infection with tubercle bacilli.

Methods for the inoculation and bleeding of mice, for the assay of interferon in L-cells using the plaque-reduction method with vesicular stomatitis virus (VSV), and for the preparation and standardization of inocula containing *B. abortus* or NDV have been described in detail previously^{1,3}. The endotoxins used were prepared from different strains of *E. coli* (0111:B4, 0113, or K235) and had similar potencies when measured by LD₅₀ determinations or interferon appearance in the plasma. Interferon titres were expressed as the dilution of plasma which would reduce the plaque count to 50 per cent of that of the controls and were calculated by probit analysis.

Preliminary studies showed that mice given 250 µg of endotoxin intravenously exhibited the usual pattern of peak interferon levels in the plasma 2 h later¹; however, a second dose of endotoxin given 48 h later failed to produce circulating interferon. To further document and extend this observation, the following experiment was performed using challenge with NDV as well as endotoxin. A large group of mice was injected intravenously with 125 µg of endotoxin. Forty-eight hours later these animals were challenged intravenously with either a second dose of 125 µg of endotoxin or with 5×10^7 plaque-forming units of NDV. Control mice which had received no prior endotoxin were also challenged with endotoxin or NDV as described. Because of the different time patterns of appearance of interferon, blood samples were obtained at 2, 4 and 6 h in the case of endotoxin challenge and at 2, 6 and 12 h from animals injected with NDV. The results presented in Fig. 1 show that prior treatment with endotoxin completely eliminated the characteristic appearance of interferon which followed endotoxin inoculation of untreated mice. In the case of NDV challenge, mice treated 48 h previously with endotoxin showed a markedly depressed interferon titre compared to the untreated controls. The untreated mice showed significant interferon

levels 2 h after injection of NDV. However, mice pre-treated with endotoxin did not produce a detectable level of interferon until 6 h after stimulation. At 12 h after inoculation of NDV, the interferon titre in control mice was 1:2,500, while in mice pretreated with endotoxin the titre had reached only 1:140. It is of interest to note that, although the levels of circulating interferon in the two groups of mice were significantly different, the rate of interferon increase after 6 h was the same.

Another experiment was performed in which mice were injected with different amounts (50 or 250 µg) of endotoxin and challenged 48 h later with a large dose (1,000 µg) of endotoxin, *B. abortus*, or decreasing amounts of NDV. The results obtained are summarized in Table 1. It is

Fig. 1. Effect of prior injection with endotoxin on interferon titres of plasma pools from mice at different times after intravenous injection of endotoxin or Newcastle disease virus (NDV). (Groups injected as follows: O, no prior treatment, 125 µg endotoxin; ●, pretreatment with 125 µg endotoxin 48 h before 125 µg endotoxin; Δ, no prior treatment, 5×10^7 plaque-forming units of NDV; ▲, pretreatment with 125 µg endotoxin 48 h before 5×10^7 plaque-forming units of NDV)

clear that both doses of endotoxin produced hyporeactivity although the higher dose (250 μ g) was much more effective. In addition, decreased interferon responses were demonstrable in animals challenged with *B. abortus* as well as with endotoxin and NDV. It should be noted that no significant change in lethality of endotoxin was found in mice 48 h after the original dose of endotoxin.

The possibility was considered that circulating humoral factors present 48 h after endotoxin injection were responsible for the hyporeactive state. To test this in the case of endotoxin, 50 mice were injected intravenously with 250 μ g of endotoxin; 48 h later, the survivors were bled and plasma collected and pooled. Before transferring this plasma pool to recipient mice, tests of the plasma pool showed that no residual interferon was detectable, eliminating the possibility of transfer of interferon to the recipients. Ten uninoculated mice received intraperitoneally 1 ml. of the donor plasma pool. Six hours later these mice and control mice were injected with 1,000 μ g of endotoxin; 2 h later they were bled to determine the interferon content of their plasmas. Control mice had received plasma from untreated mice rather than from mice treated with endotoxin. No difference was noted in the interferon content of plasmas from the two groups of animals following the endotoxin challenge. These results tend to rule out the possibility of a circulating humoral factor which might mediate the lack of response to the second dose of endotoxin.

Table 1. APPEARANCE OF INTERFERON FOLLOWING INJECTION OF ENDOTOXIN, *B. abortus*, AND NDV IN CONTROL MICE AND IN MICE INJECTED 48 h PREVIOUSLY WITH A SINGLE DOSE OF *E. coli* ENDOTOXIN

Challenge of mice at 48 h with	Interferon titre of plasma of mice injected 48 h previously with:		
	Saline (0.1 ml. i.v.)	50 μ g endotoxin (i.v.)	250 μ g endotoxin (i.v.)
Endotoxin (1,000 μ g)	1,750†	45	<16
<i>B. abortus</i> (1.5 $\times 10^8$ viable units)	560†	70	<16
NDV (4.1 $\times 10^8$ P.F.U.)	1,400†	1,100	330
NDV (4.1 $\times 10^7$ P.F.U.)	860	350	200
NDV (4.1 $\times 10^6$ P.F.U.)	50	55	<16
Saline (0.1 ml. i.v.)	<16	—	—

* Mice challenged with endotoxin were bled 2 h after injection.

† Mice challenged with *B. abortus* or NDV were bled 10 h after injection. The lot of endotoxin used in this experiment had an LD_{50} of 420 μ g.

Previous experience using passively transferred anti-NDV chicken serum in mice showed that interferon did not appear following NDV injection into recipients with circulating antibodies (Table 2). To test for the presence of virus-neutralizing substances in mice which had been rendered hyporeactive to endotoxin and NDV, the following was done. Mice were injected with 125 μ g of endotoxin (Fig. 1); 48 h later they were bled without challenge and their plasmas were tested for NDV-neutralizing activity by a plaque-reduction method using chick embryo fibroblast cultures. No NDV-neutralizing activity was found. This result eliminated antibody as the mediating factor in decreased reactivity to NDV.

Table 2. EFFECT OF PASSIVE IMMUNIZATION OF MICE WITH ANTI-NDV SERUM ON INTERFERON TITRES FOLLOWING INTRAVENOUS INJECTION OF NDV

Treatment	Interferon titre of plasma at	
	4 h	12 h
Anti-NDV chicken serum†	<16†	<64†
Normal chicken serum*	256	>4,096

* One ml. serum injected intraperitoneally 18 h prior to challenge with 5×10^7 plaque-forming units of NDV.

† Plasma from passively immunized mice prior to challenge with NDV showed a neutralizing titre of 1:1,250 by the plaque-inhibition method using chick embryo fibroblasts as host cells.

‡ Lowest dilution tested.

In order to determine whether or not prior injection of NDV would result in decreased interferon stimulation by endotoxin, a large group of mice was injected intravenously with 2×10^8 plaque-forming units of NDV. The titre of interferon in representative animals was determined using plasmas obtained 2, 6, 12, 24, 48 and 72 h after inoculation of virus. At 48, 72 and 144 h after

Fig. 2. Influence of prior injection of NDV on interferon response of mice to endotoxin. Interferon titres following injection of 2×10^8 plaque-forming units of NDV (O); a challenge dose of 500 μ g of endotoxin was given at 48, 72, and 144 h and plasmas were collected 2 h later (see bars)

the single dose of NDV, virus-treated and control mice were injected intravenously with 500 μ g of endotoxin; 2 h later these animals were bled and their plasmas tested for interferon. The results of this experiment, presented in Fig. 2, show that NDV effectively decreased interferon response to endotoxin. This decreased response to endotoxin did not disappear until between 72 and 144 h after injection of NDV. It should be noted that 48 h after virus injection there was a residual interferon titre of 1:45 in the plasma and no additional interferon was detected after endotoxin inoculation; in control mice the same dose of endotoxin produced a titre of 1:1,100. At 72 h after NDV inoculation, when no detectable residual interferon was present in the circulation, there was about 90 per cent inhibition of interferon appearance in virus-treated mice as compared with controls. By 144 h after NDV injection, full reactivity to endotoxin had returned. The preceding experiments show: (1) that the decreased appearance of interferon in hyporeactive animals is not limited to the material used to produce this state; (2) that no detectable humoral factor is responsible for the decreased interferon response induced by the injection of endotoxin or NDV.

Hyper-reactivity, the enhanced state of responsiveness to the lethal and pyrogenic effects of endotoxin, is known to occur in mice infected with attenuated tubercle bacilli⁴. Results are presented here to show that infection with *M. tuberculosis*, strain B.C.G., increases the reactivity of mice to endotoxin when measured by interferon response as well as by lethality. Mice were infected intravenously with 0.1 mg of a 10-day culture of B.C.G. grown in a modified Dubos-Middlebrook medium⁵. Fourteen days later, LD_{50} determinations with endotoxin were made using infected and un-infected mice. In addition, groups of infected and control mice received different doses of endotoxin, and interferon determinations were made with plasmas

Table 3. INFLUENCE OF HYPER-REACTIVITY FOLLOWING BCG INFECTION ON INTERFERON TITRES FOLLOWING DIFFERENT DOSES OF *E. coli* ENDOTOXIN

Group	LD_{50} of endotoxin	Amount of endotoxin used for interferon stimulation		Interferon titre of plasma at 2 h
		(μ g)	(LD_{50})	
B.C.G.-infected mice (infected 14 days prior to testing)	23 μ g	32	1.4	>4,096
		3.2	0.14	2,300
		0.32	0.014	120
		0.032	0.0014	<16
Un-infected mice	540 μ g	500	0.9	>2,048
		50	0.09	200
		5	0.009	200
		0.5	0.0009	30

obtained from bleedings 2 h later. The results are shown in Table 3. The mice infected with B.C.G. showed a 23-fold increase in sensitivity to the lethal effects of endotoxin. Associated with this, infected mice demonstrated a markedly enhanced ability to produce interferon following decreasing doses of endotoxin. For example, in infected mice 3.2 µg of endotoxin produced the same interferon titre as 500 µg in un-infected animals. Additional experiments, in which the degree of hyper-reactivity varied depending on the duration of infection, confirmed the correlation between heightened interferon-levels and increased sensitivity to the lethal effects of endotoxin.

The appearance of interferon in the circulation following the injection of *B. abortus* and NDV was tested in B.C.G.-infected mice which were hyper-reactive to the lethal and interferon-stimulating effects of endotoxin. No significant differences were found in the responses of infected and control mice to *B. abortus* and NDV over a wide dose-range.

The experiments which have been described indicate that the appearance of interferon in the circulation of mice can be affected by procedures which alter responsiveness to the lethal and pyrogenic effects of endotoxin. Hypo-reactivity produced with endotoxin inhibited responsiveness, as measured by interferon-levels, to endotoxin, *B. abortus*, and NDV; moreover, prior inoculation of

NDV markedly reduced interferon stimulation by endotoxin. These results indicate the likelihood that the same cells, probably phagocytic, are involved in the release of interferon following both types of stimulation, despite the different time patterns of appearance of interferon in the circulation¹.

In the case of hyper-reactivity to endotoxin elicited by infection with tubercle bacilli, it is apparent that the increased lethality of endotoxin is accompanied by an increased capacity of small doses of endotoxin to elicit interferon. The lack of a parallel increase in response to different doses of *B. abortus* or NDV in B.C.G.-infected mice is not explained by the results presented here and is being investigated further.

We thank Nancy Arnold, Velma Axelrod, Marion Kelly, Theodora Koshar, Gretchen McIntyre and Gloria Simon for their assistance. Endotoxin was provided through the generosity of Dr. A. I. Braude (University of Pittsburgh) and Dr. F. McIntire (Abbott Laboratories).

The work was supported by grants AI-03561 and AI-06264 from the U.S. National Institutes of Health.

ALLOGENEIC INHIBITION OF TUMOUR CELLS BY *IN VITRO* CONTACT WITH CELLS CONTAINING FOREIGN H-2 ANTIGENS

By K. E. HELLSTRÖM, I. HELLSTRÖM and C. BERGHEDEN

Institute for Tumour Biology, Karolinska Institutet Medical School, Stockholm

HOMOZYGOUS tumour cells grow in a higher frequency and after a shorter latency period when small cell numbers are transplanted to syngeneic hosts than to 'semi-syngeneic' F_1 hybrids¹⁻³. This phenomenon has been designated by the term 'syngeneic preference' in relation to the homozygous host and 'allogeneic inhibition' with reference to the F_1 hybrid host⁴.

Allogeneic inhibition could not be explained by a host-versus-graft reaction against hypothetical antigens which might have been present in the homozygous cells and hosts but absent from the F_1 hybrid hosts, since pre-irradiation of the F_1 animals did not abolish the difference and since pretreatment of the F_1 hybrids prior to grafting with normal or tumour cells of the homozygous strain did not influence allogeneic inhibition⁵. Tissue culture experiments showed that cell extracts or homogenates containing foreign histocompatibility antigens inhibited the growth of explanted target cells, suggesting that allogeneic inhibition *in vivo* might be due to the contact between the grafted tumour cells and the foreign isoantigens of the host^{5,6}. This hypothesis was subjected to further test in the present article. Neutralization experiments were made in which lymphoma cells were exposed *in vitro* to spleen or tumour cells, containing foreign H-2 antigens, and their outgrowth in syngeneic hosts was measured after subsequent implantation. Furthermore, tissue culture experiments were performed, in which explanted tumour cells were followed for the development of cytopathic changes after exposure to lymphoma cells, containing H-2 antigens of the syngeneic or allogeneic type.

Neutralization experiments. Four isoantigenic variant sub-lines were used, all derived from the *LNSF* lymphoma (of $A/Sn \times A.SW F_1$ hybrid origin). Three lines, designated *LNSFSC*, *LNSFSD* and *LNSFSE*, had been selected from *LNSF* for compatibility with the *A.SW* parental strain, and permanently lacked detectable H-2

antigens specific for the *A* strain⁵. One line, *LNSFAD*, had been selected from *LNSF* for compatibility with strain *A*. It lacked detectable H-2 antigens that were specific to the *A.SW* strain⁵. The variant lines were propagated by serial transfer in syngeneic mice (*A.SW* or *A*, respectively) during 1-10 passages.

The technique used for the neutralization tests was a modification of one described by Klein and Sjogren⁷. *A.SW*-compatible variant tumours (*LNSFSC*, *LNSFSD* or *LNSFSE*) were gathered from syngeneic (*A.SW*) mice and cell suspensions were prepared mechanically and diluted in balanced salt solution to give a concentration of 10^4 or 10^5 cells per ml. Similar suspensions were prepared from the spleens of adult, untreated mice of various genotypes (*A*, *A.BY*, *A.SW*, *CBA*, *A.SW* \times *A F_1*, *A.SW* \times *A.BY F_1*, *A.SW* \times *CBA F_1*). Among these strains *A*, *A.SW* and *A.BY* are congenic resistant lines, differing at the H-2 locus⁸. Within each experiment spleens were taken from mice of the same sex (mostly virgin females), weight and age. After washing, the spleen cells were diluted to a final concentration of 10^6 blue unstained cells/ml. In half the experiments they were irradiated *in vitro* immediately after preparation of the cell suspension with an X-ray dose of 1,000 r. (or in two experiments up to 10,000 r.). Tumour and spleen cells were mixed in equal volumes and Wellcome phytohaemagglutinin (PHA) added in a final concentration of 1:100 to establish a close contact between the tumour and spleen cells^{9,10}. The mixtures were thoroughly shaken and incubated for 45 min at 37° C. Afterwards they were inoculated subcutaneously to adult *A.SW* mice to yield a total number of 10^3 or 10^4 tumour cells inoculated per mouse. The recipient mice had been irradiated with 350 r. immediately before inoculation in order to decrease their own immunological reactivity. They were inspected 2-3 times weekly for tumour development, three diameters

Fig. 1. Neutralization of lymphoma cell outgrowth in syngeneic mice, pre-irradiated with 350 r, after exposure to untreated or X-irradiated spleen cells and phytohaemagglutinin *in vitro*. In each group of experiments 6-8 mice were inoculated

of any tumours appearing being measured and the geometric means calculated.

Fig. 1 shows that allogeneic and F_1 hybrid spleen cells inhibited the outgrowth of the lymphoma lines, as compared to syngeneic spleen cells. When unirradiated spleen cells were added, F_1 hybrid cells were slightly less effective than allogeneic cells. Pre-irradiation of the spleen cells minimized this difference by decreasing the inhibitory effect of the allogeneic cells but scarcely affecting the effect of F_1 hybrid cells.

The demonstration of allogeneic inhibition after contact of tumour cells with spleen cells, carrying foreign $H-2$ isoantigens, led to experiments where the spleen cells had been replaced with tumour cells. This was done in order to test the possibility that neutralization as observed after addition of spleen cells was due to an immunological reaction of the added cells not sensitive to X-irradiation. Experiments were performed in a similar manner as when spleen cells were added. Two variant lines derived from *LNSF* were used, namely, *LNSFAD*, compatible with strain *A* and lacking $H-2$ antigens of *A.SW* origin, and *LNSFSE*, compatible with *A.SW* and lacking $H-2$ antigens of *A* origin. In each experiment, suspensions containing 10^4 or 10^5 untreated lymphoma cells of one type were mixed with an equal volume containing 10^8 lymphoma cells of the other type which had been rendered incapable of multiplication by X-irradiation with 15,000 r.; in controls, irradiated lymphoma cells of the syngeneic type were added. After incubation in the presence of PHA the mixtures were inoculated in mice, syngeneic to the untreated cells, 6-8 mice being inoculated in each experimental group. In part of the experiments, the irradiated cells were ultrasonically disintegrated before they were added to the untreated lymphoma cells.

A total of four neutralization experiments were performed with added lymphoma cells (or cell extracts) and gave similar results, as exemplified by the experiment presented in Fig. 2. It appears that exposure of *LNSFAD* cells (*A*-compatible) to *LNSFSE* cells (*A.SW*-compatible)

Fig. 2. Neutralization of outgrowth of lymphoma variants *LNSFAD* and *LNSFSE* in syngeneic (*A* and *A.SW*, resp.) mice after exposure to X-irradiated (15,000 r.) intact and ultrasonically disintegrated *LNSFAD* and *LNSFSE* cells. In each group of experiments 6 mice were inoculated

* Cultures were observed for development of cytopathic changes after addition of 2 × 10⁷, 10⁷ and 5 × 10⁶ syngeneic or allogeneic lymphoma cells and compared with untreated control cultures, consisting of monolayers of apparently healthy cells. They were recorded as follows: 5, treated cultures better than untreated controls; 4, no difference between treated cultures and untreated controls, 3, approximately 25 per cent of cells destroyed; 2, approximately 50 per cent of cells destroyed; 1, only a few cells surviving; 0, all cells destroyed. The Table shows the mean of records given to a minimum of 3 Petri dishes which had been exposed to the same treatment.

† *LNSFAD* and *LNSFSD* cells were gathered from A × A.SW F₁.

‡ Ratios were calculated between records with added syngeneic as compared to allogeneic lymphoma cells (allog. ly. c.).

inhibited the outgrowth of *LNSFAD* and that growth of *LNSFSE* was inhibited after contact with intact or disintegrated *LNSFAD* cells.

The neutralization experiments demonstrate that differences between homozygous and F₁ hybrid mice with regard to general host factors such as endocrine balance, immunological reactivity or hybrid vigour cannot account for allogeneic inhibition. The finding that tumour outgrowth was inhibited, both by pre-irradiated F₁ hybrid spleen cells and by intact or disintegrated lymphoma cells carrying foreign *H-2* antigens, gives increased weight to the hypothesis that allogeneic inhibition depends on a close contact between cells carrying different histocompatibility antigens, and thus having a different surface structure⁶. This is also strengthened by (unpublished) experiments where the inhibitory effect of added allogeneic or F₁ hybrid cells was abolished if their *H-2* antigens were specifically covered with antibodies.

Tissue culture experiments. *In vitro* experiments were performed in order to definitely exclude all influence of the host animal on neutralization of tumour growth as observed after addition of cells carrying foreign *H-2* antigens. Transplanted tumours of A or A.SW origin were explanted and the cultures were exposed to added lymphoma cells from A- or A.SW-compatible variant sub-lines, selected from *LNSF*. Three kinds of tumour cells were explanted: S1A, MWE and YAA-C1-C3. S1A is a mammary carcinoma of A origin, MWE a sarcoma of A.SW origin and YAA-C1-C3 a cloned lymphoma of A origin¹¹. Explantation was made into 50-mm 'Falcon' plastic Petri dishes, each Petri dish being seeded with 3 × 10⁶ tumour cells. About 24 h after seeding, the culture medium was decanted and suspended lymphoma variant cells of the *LNSFAD* (A-compatible) or *LNSFSD* (A.SW-compatible) lines were added in 0.2-ml. volumes to each Petri dish, the lymphoma suspensions containing between 2.5 × 10⁷ and 10⁸ cells per ml. In addition, 0.2 ml. PHA, diluted 1:20, was added. After 45 min incubation at 37° C, 4-ml. culture medium, containing 20 per cent heat-inactivated calf serum in Earle's solution, was added to each Petri dish, and the dishes were incubated in a 5 per cent carbon dioxide-air atmosphere. The Petri dishes were followed for appearance of cytopathic changes, which were recorded as stated in the footnote to Table 1. A minimum of three Petri dishes were used for each kind of treatment. All dishes were given coded numbers at the time of addition of the

lymphoma cells, the code being unknown to the persons observing the cultures.

Findings are presented in Table 1. Addition of lymphoma cells containing *H-2* antigens, allogeneic to the explants, consistently produced cytopathic changes in the explanted cells with very small variation between individual Petri dishes, exposed to the same type and number of lymphoma cells. The fact that both lymphoma lines (*LNSFAD* and *LNSFSD*) were gathered from A × A.SW F₁ hybrid mice and tested on tumours for which they were syngeneic and allogeneic, respectively, excludes influence of normal stroma cells of host origin on the results. It follows that the cytopathic changes detected after exposure of explanted cells to allogeneic lymphoma variants are scarcely a consequence of immune reactions of the added cells, unless the assumption is made that the lymphoma cells are capable of immunological reactivity; the fact that neither pre-irradiation nor ultrasonic disintegration of the lymphoma cells abrogated their ability to neutralize tumour growth *in vivo* excludes the latter possibility. Both neutralization and tissue culture experiments therefore strongly support the hypothesis that allogeneic inhibition of tumour growth is a consequence of target cell contact with foreign *H-2* isoantigens⁶. It is suggested that allogeneic inhibition may function as a surveillance mechanism, capable of eliminating cellular variants, the (*H-2*) antigenicity of which differs from the general pattern within a given tissue, without necessary engagement of immunologically competent cells.

SPECIFIC UPTAKE IN CORPORA LUTEA OF A NON-STEROID SUBSTANCE WITH ANTI-GESTAGENIC PROPERTIES

By ÅKE HANNGREN, NIELS EINER-JENSEN and SVEN ULLBERG

Department of Medicine, Karolinska Hospital, and Department of Pharmacology, Royal Veterinary College, Stockholm, Sweden

CERTAIN unsymmetrical diphenylalkenes have been found to possess the ability to interfere with the vaginal oestrous reaction induced by oestradiol benzoate^{1,2}. Among these substances, *bis*(*p*-hydroxyphenyl)-cyclohexylidenemethane (compound 'F6060', Fig. 1) has an oestrogenic activity only about 1/1,000 that of oestradiol benzoate.

Fig. 1

In clinical investigations it was found that the acetylated form of the compound (Compound 'F6066') had an effect on prostatic cancer similar to conventional oestrogens but without the feminizing side-effects³. In postmenopausal women a depression of the output of oestradiol-17 β and changes in the relation between excreted FSH and LH were found⁴.

By determining the body distribution of the compound it was hoped to gain further information regarding their site of action. The substances were labelled with ¹⁴C at the α -carbon⁵. The specific activity was about 10 μ C/mg.

The compounds, which were synthesized by Ferrosan, Ltd., Sweden, were dissolved in absolute alcohol and mixed with water containing 'Tween 80' (5 per cent).

Female mice, non-pregnant and pregnant in a late stage of gestation, were used. A dose of 0.8 mg corresponding to 8 μ C was given intravenously. The mice were killed by rapid freezing at the following intervals after injection: 5 min, 20 min, 1 h, 4 h and 24 h.

20- μ sections at various levels through the whole animal were taken at -10°C. The sections were freeze-dried and pressed against Gevaert 'Structurix D 7' X-ray film⁶.

The autoradiograms showed a remarkably strong and selective accumulation of radioactivity in corpora lutea after only 5 min (Fig. 2). This accumulation was still prominent after 20 min (Fig. 3) and then decreased successively but was still apparent after 24 h (Fig. 4). It was most pronounced in the pregnant mice. In non-pregnant mice the accumulation in corpora lutea varied, probably owing to different functional states.

A selective accumulation was also noticed in part of the placenta. The activity was confined to the visceral yolk sac epithelium and was seen from 1 to 24 h (Fig. 4) with a peak at 4 h. From this time and during the whole observation period it showed the highest activity in the body. A detailed description of the autoradiographic results will be published elsewhere.

The influence of 'F6066' on early pregnancy was tested in rats and rabbits. Groups of six female rats were caged together with males, two females to one male. On the first and second day the females were injected subcutaneously with an oil solution of 'F6066'. The injections were then repeated three times at weekly intervals. If pregnancy was observed the animals were killed just be-

Table 1. ANTI-FERTILITY IN RATS

	No. of pregnancies per 6 animals	No. of fully developed foetuses per 6 animals
Olive oil	5	51
1 mg/kg/day 'F6066'	4	41
5 mg/kg 'F6066'	1	11
25 mg/kg 'F6066'	0	0

fore parturition. On the day of the last injection the males were removed and 3 weeks later all females were killed for examination of possible pregnancy and number of living foetuses. The results are presented in Table 1. The number of living foetuses decreased with increased dose. The highest dose used was <1.5 per cent of the acute LD₅₀.

In a modified Clauberg test, immature female rabbits (600-800 g) were primed with 0.5 μ C oestradiol benzoate for 7 days. From days 8 to 14 they were all injected with 0.2 mg progesterone in olive oil, subcutaneously, and half of them also received 'F6066' simultaneously, on days 8-14 or days 13-14.

In the Clauberg test, injections of oestrogens produce a proliferation of the endometrium. Progesterone injections

Fig. 2. Autoradiogram (b) showing the distribution of ¹⁴C-'F6060' in ovary, fallopian tube and pregnant uterus 5 min after intravenous injection. Corresponding tissue section (a) is stained by haemalum-eosin. Note the very high concentration in corpora lutea. No activity in the foetus

Fig. 3. Whole-body autoradiogram from a pregnant mouse 20 min after intravenous injection of ¹⁴C-'F6066'. Note high radioactivity in corpora lutea and liver

transform this to a secretory endometrium. Simultaneous administration of 1 mg 'F6066' from days 8 to 14 prevented the development of the secretory endometrium. If 5 mg 'F6066' was injected on days 13 and 14, when the secretory phase was established, a regression could be seen (Figs. 5 and 6).

The present investigation has shown that the substances have: (1) a selective and high accumulation in corpora lutea; (2) an anti-fertility activity in rats; and (3) an anti-progesterone effect in the Clauberg test.

The strong affinity for corpora lutea is unique and may indicate an interference with progesterone production. The lack of accumulation in some corpora lutea may indicate that the affinity is not related to the cell-type as such but to the intensity of hormone production.

On the other hand, the Clauberg test shows that the substances interfere with the effect of injected progesterone, that is, have a peripheral effect on a target organ. It is known that natural oestrogens and stilboestrol have similar properties. Thus the observed effect may be due to the weak oestrogenic activity. In the anti-fertility tests, however, the autopsies after administration of 'F6066' did not show the large volume of sanguinary fluid in the uterine cavity that is often seen after stilboestrol-induced abortion.

Fig. 4. Autoradiogram showing the distribution of ^{14}C -'F6060' in a pregnant mouse 24 h after intravenous injection. Note high radioactivity in the visceral yolk sac epithelium. Radioactivity is seen in 5 corpora lutea. Three placentae and foetuses show no radioactivity.

Fig. 5. Endometrium of rabbit uterus on day 15 after administration of 0.5 µg oestradiol benzoate on days 1-7, and 0.2 mg progesterone on days 8-14.

Fig. 6. Endometrium of rabbit uterus on day 15 after administration of 0.5 µg oestradiol benzoate on days 1-7, 0.2 mg progesterone on days 8-14 and 5.0 mg 'F6066' on days 13 and 14.

The observations made may indicate interference with gestagen production as well as an inhibition of the gestagen effect on target organs. The accumulation found in the yolk-sac placenta may be explained as a foetal excretory event, but interference with progesterone synthesis may also be considered.

Laboratory equipment used in this investigation was kindly supplied by Ragnar och Torsten Söderbergs stiftelser.

AN INSECT 'BITOMETER'

By PHILIP KASHIN and HAROLD G. WAKELEY

Life Sciences Research Division, IIT Research Institute, Chicago, Illinois

THE methods at present used to examine biting by mosquitoes are chiefly limited to direct visual observation^{1,2}, or to the measurement of engorgement by changes in weight or radioactive tracer intake after the mosquito has bitten³⁻⁵. In determining the attractant

or repellent properties of a compound based on the method of engorgement, there is no way to determine whether a mosquito has penetrated into and salivated in the skin of a host unless engorgement occurs. The degree of repellency attributed to a compound can be erroneously

sessed if a mosquito penetrates the skin of a host and salivates, but does not engorge. On the other hand, the method of direct visual observation is laborious, uncertain, and in many cases impractical. Since salivation is the factor by which mosquito-borne disease is disseminated, the measure of repellency of a compound by the degree of engorgement is seriously limited.

Through a new assay procedure recently developed in our laboratories, the various phases of the mosquito bite from the initial penetration of the mouth-parts to final withdrawal can be detected electronically.

It was reasoned that the contact between mosquito and its host could be used to form an integral part of a series electrical circuit, where the insertion and withdrawal of the mosquito's mouth-parts in relation to the host could be used as the making and breaking switch in the circuit.

Since it is impracticable to connect a wire directly to a mosquito, a 50- or 100-mesh bronze screen is used to separate the mosquito from its host. The screen covers a 1-pint round ice-cream carton (or glass container if simultaneous visual observation is desired).

Female *Aedes aegypti* L. are placed into the container. The screen is connected by a soldered lead to resistances totaling 16 M Ω , and then to the negative pole of a 1.35-V standard mercury cell (Mallory mercury battery, RM-1-R). The positive pole of the battery is connected to the input of a suitable recording instrument. The recorder is a Sanborn model 320 two-channel general-purpose recorder (Sanborn Co., Waltham, Massachusetts).

The circuit passes through the recorder and is carried by another lead from the recorder to the tail of an anaesthetized mouse (the host), where it is embedded via a hypodermic needle soldered on to the lead. The mouse is placed on top of the bronze screen, belly down. Contact of the mouse's paws with the screen is carefully avoided. The hair on the mouse's body is sufficient to insulate the mouse from the screen, and no current flows. The entire circuit is thus connected in series (Fig. 1). The wiring diagram of the box which contains the resistors and the battery is shown in Fig. 2.

When a mosquito bites the mouse, the mosquito holds on to the wire screen with its legs and passes its proboscis through the spaces of the mesh and into the mouse. When the skin of the mouse is penetrated, the circuit between the mouse and the screen is completed through the mosquito. The resulting flow of current is registered by a displacement of the writing stylus of the recorder. The current flows continuously so long as the mosquito

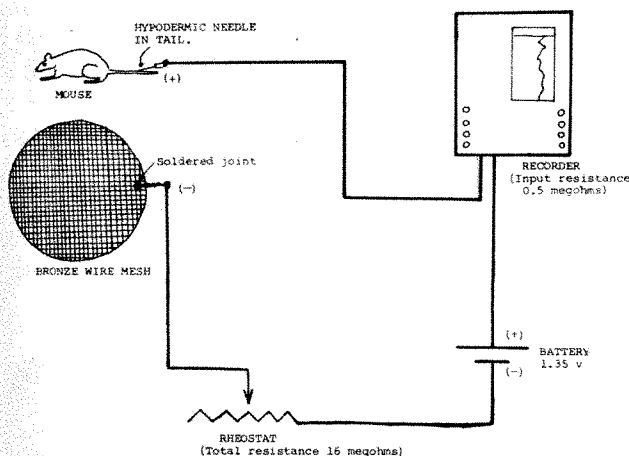

Fig. 1. Circuit diagram of apparatus

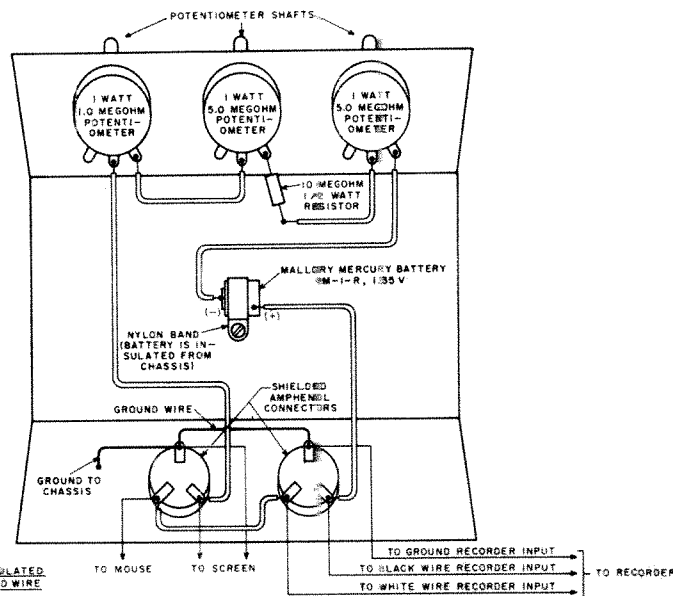

Fig. 2. Wiring diagram of resistor-battery box

is completing the circuit, and the stylus is displaced from the base line (point of no current flow) on the recorder chart paper for the entire time the mosquito is biting. When the proboscis is withdrawn, the circuit is broken. The writing stylus immediately returns to the base line, indicating that virtually infinite resistance has been re-established between the mouse and the bronze mesh.

The question of whether the flow of an electric current could change a mosquito's behaviour or create artefacts in the system was considered. A calculation taking into account the total resistance of the circuit and the total voltage available showed that a maximum of 8.2×10^{-8} amp is available in the circuit, assuming no resistance between the mouse and the mesh. The average displacement of the stylus is 10 mm from the base line when a single mosquito bites a mouse through the screen. In calibrating the recorder (which was always set at its highest sensitivity level of 0.5 mV/mm and maximum gain), it was observed that a displacement of 3.4 mm from the base line is equivalent to 1 mV. A displacement of 10 mm (equivalent to an average single mosquito bite), therefore, indicates a voltage drop of 2.94 mV across the recorder.

From the known input resistance of the recorder (0.5 M Ω), and the measured voltage drop across the recorder when a mosquito bites, it can be shown that approximately 6.0×10^{-8} amp flows through a mosquito at the time of the bite. This is probably an over-estimation, since the resistance of the mosquito is not taken into account. This is an extremely small quantity of electricity, and is probably no more than the static electrical charge that the insect attains during free flight. We therefore consider that no artefacts that might affect a mosquito's activities are introduced by this flow of electrical current. We could not detect changes in a mosquito's behaviour even when all resistances were removed from the circuit. A value of 16 M Ω of resistance between the mesh and the battery seemed to give the most uniform recordings.

The question of whether biting was the only activity that could cause a departure from the base line in the recording was also considered. When male *Aedes aegypti* L. mosquitoes or female mosquitoes whose proboscises were amputated were placed in the mesh-covered container, no displacement from the base line was observed at any time. We therefore conclude that it is only the biting female mosquito which causes displacement.

A visual observation and an electronic recording were made simultaneously during the course of a single mosquito bite. The patterns recorded during the observed

probing activities of the mosquito were generally irregular (left side of Fig. 3). When the mosquito was observed to be in the biting attitude, the chart recording was much more regular (right side of Fig. 3). Engorgement was observed during the more regular phase of the recording. When the mosquito was fully engorged after about 1.5 min the proboscis was withdrawn from the mouse and the stylus immediately returned to the base line on the chart recording (Fig. 4).

When about 50 mosquitoes were placed in the container and permitted to bite simultaneously, the pattern was very irregular (Fig. 5). The departure from the base line was greater than seen with a single mosquito bite. This greater departure is expected, since the resistance between the mouse and the mesh during the biting of a group of mosquitoes is less than during the biting of a single mosquito. However, proportionality of stylus displacement could not be detected for the bites of succeeding mosquitoes. The first mosquito that bites changes the resistance of the system from an infinite to a finite value. Subsequent bites do not cause as large a change, and proportionality should therefore not be expected. In effect, when a group of mosquitoes bite, a number of miniature parallel circuits are set up between the mouse

Fig. 6. Removal and replacement of mouse on mesh during biting by a group of mosquitoes

and the mesh. Assuming the resistances of all the mosquitoes are equal, each biting mosquito should draw the same quantity of current. In terms of amps, then, proportionality and additivity might be expected as the number of parallel units (biting mosquitoes) in the circuit increases. We are at present examining methods to quantify the apparatus so that the number of insects biting simultaneously can be ascertained.

During the recording of a group of mosquitoes biting simultaneously, the mouse was removed from the mesh causing all the probosces to be withdrawn from the mouse, and then replaced. Fig. 6 shows that, after the mouse was replaced on the mesh, the base line reverted to its original position. It was displaced again about 1.5 sec later when the mosquitoes resumed their attack on the mouse.

By changing the mesh size of the screen or the host animal, the apparatus can be adapted to determining the biting activities of many species of biting and blood sucking insects, and the attractant, repellent and insecticidal properties of various compounds can be determined. By allowing the recorder to run overnight, or for a longer period of time, the duration of effective activity of a compound can be automatically monitored. The recorder is also capable of portable operation with a battery converter and can therefore probably be adapted for operation under actual field conditions.

This work was supported by the U.S. Army Medical Research and Development Command, Department of the Army, under research contract DA-49-193-MD-2281.

Note added in proof. A paper by McLean and Kinsey (*Nature*, 202, 1358; 1964) describing a technique for recording electronically aphid feeding and salivation has recently come to our attention. Though similar in concept, the instrumentation, electrical circuitry, applications, and sensitivities of these techniques are different.

SYNTHESIS OF RIBOSOMAL RNA IN SYNCHRONIZED HELA CELLS

By PROF. MATTHEW D. SCHARFF and DR. ELLIOTT ROBBINS

Departments of Cell Biology, Medicine, Neurology and Microbiology, Albert Einstein College of Medicine, Bronx, New York

WHILE the synthesis and metabolism of ribosomal RNA in randomly dividing cultures have been described¹⁻⁵, it is not known whether these processes occur similarly in all stages of the growth cycle. Several investigators working with individual cells have demonstrated that the rate of RNA synthesis increases progressively throughout interphase⁶⁻⁸; however, in order to study the synthesis of the different molecular species of RNA large numbers of synchronized cells are necessary. Using a method of synchronization^{6,9} which avoids the

ambiguities introduced by employing physical and chemical inhibitors, we have related the synthesis of high molecular weight and ribosomal RNA to various stages of the cell's life-cycle.

Suspension cultures of synchronized S3 HeLa were prepared by preferentially detaching mitotic cells from monolayers grown in Eagle's spinner medium¹⁰ supplemented with 3.5 per cent calf and 3.5 per cent foetal calf serum. Rates of synthesis of total RNA, DNA or protein were obtained by labelling 0.5-ml. aliquots of synchronized

cells in suspension for 30 min with either 0.2 μ Ci of 14 C-uridine (30 mc./mmole), 0.5 μ Ci of 14 C-thymidine (30 mc./mmole), or 1 μ Ci of a mixture of 14 C-threonine, valine and leucylalanine (100–300 mc./mmole) (New England Nuclear Corporation). The incorporation of isotope was stopped by chilling, the cells washed free of serum with Earle's saline, and the pellets treated with 5 per cent trichloroacetic acid (TCA). The acid-precipitable material was collected on Millipore filters and analysed for radioactivity in a low background gas flow counter (Nuclear-Chicago). All determinations were carried out in duplicate with a replication error of less than 10 per cent.

To characterize the species of RNA being formed, cells were exposed to 14 C-uridine for either 20 min or 2 h, washed in Earle's salts, resuspended in hypotonic buffer (0.2 M NaCl, 10^{-2} M tris-HCl pH 7.4, 1.5×10^{-3} M $MgCl_2$) and disrupted with 1 per cent sodium dodecyl sulphate (SDS). In some experiments cytoplasm was separated from nuclei by Dounce homogenization following hypotonic shock^{11,12}. Unlabelled HeLa cell cytoplasm was added to provide optical density markers and the lysates were analysed by centrifugation at 20° C through 15–30 per cent linear sucrose gradients containing 0.5 per cent SDS, 0.1 M NaCl and 5×10^{-3} M tris-HCl pH 7.4. The ultra-violet absorbance at 260 m μ was monitored with a recording spectrophotometer (Gilford) and acid-precipitable radioactivity was determined by making samples 12 per cent with TCA and processing them as already described here. Alternatively, cells were washed, resuspended in hypotonic buffer, added to HeLa cell cytoplasm, and the RNA extracted with hot phenol and SDS¹. While both techniques have given essentially the same results if less than 10^6 cells are used, extraction with SDS alone is more convenient and gives more reproducible data.

The metaphase index was determined by sedimenting a small aliquot of cells and counting the fraction in metaphase.

The life-cycle of mammalian cells has been divided into the interval between mitosis and DNA synthesis (G_1), the period of DNA synthesis (S), and the interval between DNA synthesis and mitosis (G_2)¹³. In order to relate the rates of synthesis of high molecular weight and ribosomal RNA to these stages, it was important to establish the rate of total RNA synthesis throughout interphase and its relationship to the synthesis of DNA and protein in our strain of HeLa S3 (Fig. 1). In general, the progressive increase in the rate of total RNA synthesis throughout interphase as well as the character and duration of the DNA synthesis curve confirm the findings which have been reported for single cells^{6–8}. The depression of RNA and protein synthesis in the presence of a high mitotic index immediately after synchronization (55 per cent of the cells in metaphase, 45 per cent in anaphase or telophase) and between 14 and 17 h, is

Fig. 1. Synthesis of RNA, DNA and protein. 10^6 cells in 0.5 ml. aliquots were incubated at the indicated times with 14 C-uridine, 14 C-thymidine or a mixture of 14 C-valine, 14 C-threonine and 14 C-phenylalanine for 30 min and processed as described in the text. The RNA data have not been corrected for the 8–10 per cent of the acid-precipitable 14 C-uridine counts which are found in DNA during the period of significant DNA synthesis. x, Metaphase index; Δ , 14 C-thymidine incorporation; \bullet , 14 C-uridine incorporation; \circ , 14 C-amino-acid incorporation.

Fig. 2. Synthesis of 45S RNA in G_1 , S and G_2 . Separate preparations of synchronized HeLa cells were collected at 2, 8 and 15 h prior to labelling so as to allow simultaneous processing of G_1 , S and G_2 populations. Four ml. of cells at 2×10^6 cells/ml. were incubated with 5 μ Ci 14 C-uridine for 20 min. Following washing, the cells were mixed with 1 ml. of unlabelled HeLa cell cytoplasm from 2×10^6 cells. The mixture was extracted with 1 per cent SDS and layered on linear sucrose gradients which were centrifuged for 14 h at 19,000 r.p.m. in the SW 25 swinging bucket rotor. \circ , G_1 ; Δ , S ; \bullet , G_2 .

Fig. 3. Synthesis of cytoplasmic RNA. Cells from G_1 , S and G_2 were prepared as described in the legend of Fig. 2. Two ml. from each stage was exposed to 2.5 μ Ci 14 C-uridine for 2 h, washed, and mixed with 2×10^7 unlabelled HeLa cells. Cytoplasm was prepared as described in the text and following extraction with 1 per cent SDS analysed on sucrose gradients centrifuged at 23,000 r.p.m. for 16 h. \circ , G_1 ; Δ , S ; \bullet , G_2 .

consistent with autoradiographic investigations^{14–17} and with our recent observation that the number of polysomes are greatly decreased during mitosis¹⁸.

Since mitosis lasts 30–45 min, an appreciable mitotic index persisting for several hours indicates the loss of synchrony which characteristically occurs during one division cycle. It is clear that this loss of synchrony makes it impossible to obtain a uniform population of cells which have completed DNA synthesis but have not yet entered mitosis (G_2). Because of this, cell populations which we will call G_2 are in fact contaminated with significant numbers of cells which are still synthesizing DNA or in mitosis, as well as a few which have begun a second interphase.

In randomly dividing cultures of mammalian cells most of the RNA synthesized is ribosomal RNA. Its synthesis begins with the appearance in the nucleus of a high molecular weight RNA with a sedimentation value of approximately 45S. After 20–30 min exposure to 14 C-uridine, small amounts of newly synthesized 28S and 16S RNA are also detectable and with longer labelling times 28S and 16S RNA are found in the cytoplasm in association with the 60S and 40S ribosomal sub-units respectively.

The 16S RNA enters the cytoplasm more rapidly than the 28S RNA¹⁻⁵.

Figs. 2 and 3 illustrate that these events occur at all stages in the cell-cycle. Fig. 2 shows the results of exposing cells to ¹⁴C-uridine for 20 min during G1, s and G2. For more convenient comparison of the relative quantities of the different RNA species, the data have been 'normalized' so that there are the same number of total counts per gradient. Thus, while there is less total RNA synthesized per ml. of cells in G1 than in s, this is not apparent from the curves as drawn. As can be seen, cells in G1, s and G2 synthesized primarily high molecular weight RNA during the first 20 min of exposure to label, although there was also a small amount of newly synthesized RNA in the 28S and 16S areas. In the experiment illustrated there is relatively less newly synthesized 45S RNA and more 28S and 16S RNA in G1 than in s and G2, but these differences are variable and of unknown significance; the precise height of the peak, however, is of less significance than the fact that 45S RNA is made in large quantity throughout interphase. Analysis of the cytoplasm alone (Fig. 3) further emphasizes the constant pattern of RNA synthesis during the growth cycle; after 2 h exposure to ¹⁴C-uridine, 28S and 16S ribosomal RNA as well as 4S transfer RNA are present in the same relative amounts at all stages; 16S RNA was consistently present in larger amounts due to its more rapid entry into the cytoplasm. Similar results were obtained when other time points in G1 and s were examined.

Since it has been shown that RNA is not synthesized on replicating DNA^{14,19}, it is important to consider whether a decrease in either total or ribosomal RNA synthesis should be detectable during s in synchronized HeLa cells. During the time of maximum thymidine incorporation (11.5-12 h), only 5 per cent of the total DNA was synthesized. If the replication of the 400 cistrons responsible for synthesis of ribosomal RNA²⁰ were a random process, it is clear that we would expect to see, at the most, a parallel 5 per cent drop in ribosomal RNA synthesis; this is essentially our experimental error. Even if the replication of these cistrons were not a random process and occurred during a short interval, lack of perfect cell synchrony would make detection of a decrease in RNA

synthesis difficult in our experiment; however, analysis of single cells using short exposures to label and autoradiography might resolve this question. It should be noted that while Reiter and Littlefield²¹ reported a decrease in nuclear RNA synthesis during s in chick fibroblast cells synchronized with FUDR, it does not appear that their results are applicable to untreated HeLa cells.

Perhaps more interesting is the absence of a significant increase in RNA synthesis during s. This clearly implies that either the newly synthesized DNA does not act as a template for RNA synthesis or that the pre-existing DNA is progressively repressed.

We thank Dr. A. Zetterberg for allowing us to see his manuscripts prior to publication.

HETEROGENEOUS BINDING OF ACRIDINE ORANGE BY POLYRIBONUCLEOTIDES

By PROF. R. F. BEERS, jun., and G. ARMILEI

Department of Radiological Sciences, School of Hygiene and Public Health, Johns Hopkins University, Baltimore

ACRIDINE orange (AO) binding of polyribonucleotides results in extensive stacking of the dye molecules in linear arrays along the polymer chain¹⁻³. This is attributed to a highly co-operative influence of neighbouring bound dye molecules. The dissociation constant for the first dye molecule is larger than that of the second or subsequent adjacent dye molecules. If the discrepancy between the first and subsequent dissociation constants is great enough, a given polymer chain becomes 100 per cent saturated with the dye before a second polymer chain begins to bind the dye.

Evidence for this quantum type of dye binding has been obtained in adsorption isotherm investigations with *Micrococcus lysodeikticus* and *Bacillus cereus*⁴. The fraction of cells stained orange by the dye (10 per cent of dry weight) is proportional to the amount of dye bound by a given suspension of cells, that is, the percentage saturation of the bacterial suspension is equal to the

percentage of bacterial cells saturated 100 per cent by the dye.

The molecular weight of a polynucleotide-dye complex 100 per cent saturated with AO is approximately twice that of the free polymer. Density gradient ultracentrifugation should demonstrate an increase in mobility of the polymer saturated with dye and, indeed, separate the dye-polymer complexes from the free polymer molecules⁵. Polyadenylic, polyuridylic and polycytidylic acids were purchased from Miles Chemical Co., Elkhart, Indiana. Polyadenylic acid saturated 50 per cent with AO was centrifuged in a sucrose gradient at 63,500g for 17.5 h. Fig. 1 shows the distribution pattern of the polymer (260 mμ) and of the dye (465 mμ). The slowest component, which is essentially free of the dye, has the same mobility as that of the control sample of polyadenylic acid. The faster component with a mobility approximately twice that of polyadenylic acid corresponds to the distribution

Fig. 1. Density-gradient ultracentrifugation of poly A saturated 50 per cent with acridine orange. One ml. each of 1 mM poly A and 0.5 mM acridine orange in 0.5 M *tris*, pH 7.5, were mixed and layered in a sucrose gradient 5–25 per cent. The preparation was centrifuged at 63,500g for 17.5 h. Control was performed under identical conditions without the dye. One-ml. aliquots were moved from the bottom of the centrifuge tube for measurement of their respective optical densities at 260 mμ and 465 mμ. ○, Optical density of poly A-acridine orange mixture at 260 mμ; ●, optical density of poly A-acridine orange mixture at 465 mμ; ×, optical density of poly A control at 260 mμ.

Fig. 2. Density-gradient electrophoresis of poly A saturated 50 per cent with acridine orange. One ml. sample containing 8×10^{-3} M poly A, 4×10^{-3} M acridine orange and 5×10^{-3} M phosphate buffer, pH 7.5, in 4 per cent sucrose was layered on a sucrose gradient column 4–25 per cent in 5×10^{-3} M phosphate buffer, pH 7.3. Electrophoretic run lasted 3 h at 2 m.amp and 20° C. One-ml. aliquots were removed for measurement of their respective optical densities at 260 mμ and 465 mμ. ○, 260 mμ; ●, 465 mμ.

pattern of the dye and, in fact, is 100 per cent saturated with AO. A third component sedimenting to the bottom of the centrifuge tube is an aggregate of the dye-saturated polymers. Similar results have been obtained with polyuridylic and polycytidylic acids. The fraction of polymer molecules saturated with the dye is always proportional to the amount of dye present.

Resolution of copolymers by this method has not been successful, although the peak of dye distribution measured at 465 mμ is always in advance of that of the polymer measured at 260 mμ. The observed mobility of the dye-polymer mixture increases with the degree of saturation of the polymer mixture. Copolymers were synthesized by the action of polynucleotide phosphorylase prepared from *Micrococcus lysodeikticus* cells.

Because AO is a singly charged cation at the pH ranges employed in these studies (pH 7–8), the fully saturated polymer should have a zero net charge. Therefore, it should be possible to separate the polymer components by electrophoresis. Density gradient electrophoresis studies were performed in a water-jacketed column modified after the apparatus described by Olivera *et al.*⁶ Pre-

liminary studies with zinc-free dye failed to demonstrate any separation of the components. However, with the zinc-dye complex (net charge +3) the polymer can be separated into two components. The faster component demonstrates a bright green fluorescence and the slower component a bright orange fluorescence. The former corresponds to Complex II, the latter to Complex I (ref. 2). Fig. 2 shows the distribution pattern of polyadenylic acid 50 per cent saturated with acridine orange electrophoresed in a sucrose gradient. The slower component is 100 per cent saturated with the dye. The addition of $MgCl_2$ at concentrations comparable with those of the dye reduced or abolished the resolution of the peaks. In contrast, zinc increases the resolution of the peaks.

Fig. 3 gives the distribution pattern of a copolymer of adenylic and uridylic acids with a one-to-one base ratio. Similar results have been obtained with yeast RNA. However, the extent of dye binding by the slower component is considerably less than 100 per cent.

Equal molar mixtures of polyadenylic acid, polyuridylic acid and AO, heated to 190° briefly and cooled slowly when electrophoresed in the sucrose gradient, fractionate into two components (Fig. 4). The faster component contains 80 per cent polyadenylic acid, indicating that the dye has a stronger affinity for polyadenylic acid than for polyuridylic acid.

These results suggest that the capacity of a particular copolymer to bind the dye may be a function of its base composition or sequence. To test this hypothesis, an equi-molar mixture of two copolymers having 24.5 and 86.5 per cent adenylic acid, respectively, was electrophoresed with equi-molar AO in the sucrose gradient. The faster component free of the dye had an adenylic acid content of only 47.5 per cent, indicating that the copolymer containing the higher fraction of adenylic acid preferentially bound the dye.

Similar results have been obtained with methylene blue and acriflavine. Acriflavine appears to provide a better separation of the polymer complexes. Moreover, the fully saturated dye-polymer complex does not migrate from the origin.

These investigations clearly establish for the first time the quantized nature of acridine orange binding by polyribonucleotides containing one to four different bases. Even with RNA there is no evidence of any significant

Fig. 3. Density-gradient electrophoresis of poly AU saturated 50 per cent with acridine orange. One ml. sample of 9×10^{-3} poly AU (1:1 base ratio), 4.5×10^{-3} M acridine orange, and 5×10^{-3} M phosphate buffer, pH 7.5, in 4 per cent sucrose was applied to electrophoretic column. Electrophoretic run lasted 1 h at 3 m.amp and 4° C. Experimental conditions were the same as in Fig. 2. ○, 260 mμ; ●, 465 mμ.

Fig. 4. Density-gradient electrophoresis of equi-molar mixtures of poly A, poly U and acridine orange. One-ml. sample containing 0.36 mM each of poly A, poly U and acridine orange in 4 mM phosphate buffer, pH 7.5, was heated briefly to 100° in a water-bath and cooled slowly to 4° before applying to the sucrose gradient. Electrophoretic run lasted 3 h at 3 m. amp and 4° C. Experimental conditions were the same as in Fig. 2. ○, 260 mμ; ●, 465 mμ.

random dye binding in which the dimer of the dye predominates³.

Because of these findings the effects of the dye on the kinetics of polynucleotide phosphorylase must be re-interpreted⁷. In particular the mechanism by which the fully saturated dye-polymer complex stimulates the polymerization reaction apparently involves more than a simple electrostatic effect as postulated elsewhere. The dye titration studies with various polyribonucleotides^{2,3} also

must be re-interpreted on the basis of a quantized scheme of dye binding.

The second significant observation is the dependence of the dye binding on the base ratios and possible base sequences. This suggests the possibility of using the dye as a reagent for fractionating RNA according to the base composition of the polynucleotides.

The persistent negative electrostatic charge of fully saturated AO-polymer complexes is an unexpected finding which may be accounted for by the presence of a zeta potential of the dye-polymer aggregate. These aggregates are formed reversibly but can be readily demonstrated by density gradient ultracentrifugation. Visual inspection of the electrophoretic column suggests the presence of aggregates. If this is the case the dye-polymer complexes are not in solution but exist as the solid component of a two-phase system. This would provide a physical basis for the existence of a zeta potential on the surface of these aggregates. Attempts to reverse the charge of the complexes by the addition of equi-molar Zn^{2+} were unsuccessful. During the electrophoretic run the Zn^{2+} contained in the dye migrated to the cathode, whereas the dye-polymer complex migrated to the anode.

NUCLEOTIDE PEPTIDES IN YEAST

By DR. D. J. MILLIN* and M. J. SALTmarsh-ANDREW

Brewing Industry Research Foundation, Nutfield, Redhill, Surrey

THE occurrence of complexes containing nucleotides and amino-acids has recently been reviewed¹. The best known of these are the amino-acid derivatives of transfer-RNA and the corresponding peptide derivatives now regarded as ribosomal-bound intermediates in protein synthesis^{2,3}. Complex mixtures of less-well-characterized compounds of low molecular weight are present in aqueous-ethanolic and trichloroacetic acid extracts of yeasts⁴⁻¹¹ and similar mixtures have been reported from other micro-organisms, green plants and various mammalian tissues^{1,12-14}.

Davies and Harris^{9,10} isolated several compounds from yeast and assigned structures involving phosphoanhydride bonds between the 5'-phosphate of uridylic acid and the carboxyl group of alanine. The extracts obtained from yeast were clearly very complex^{10,11}, but many of the components had broadly similar amino-acid and nucleotide composition and reduced periodate rapidly. They were thus thought to possess 5'-phosphoanhydride bonds. After mild treatment with alkali the ability of these mixtures to reduce periodate increased. This was interpreted as indicative of the presence of nucleotide peptides possessing ester bonds between the 2'- or 3'-hydroxyl group of ribose and the carboxyl group of an amino-acid¹⁵. Similar structures had been suggested by Koningsberger *et al.*^{4,6}.

During re-investigation of these preparations, attempts were made to correlate nucleotide (calculated as uridylic acid from the extinction at 260 mμ), ribose (determined by the method of Mejbbaum¹⁶ after bromination of the sample¹⁷), amount of periodate reduced¹⁵ and number of

alkali-labile 'activated' bonds. The latter were estimated by reaction with hydroxylamine at neutral pH before and after mild alkaline hydrolysis followed by determination of the hydroxamate formed¹⁸. The values thus obtained did not exceed 3 μmole/g yeast in any of the samples tested. The nucleotide- and ribose-levels were always in reasonable agreement and in excess of the alkali-labile 'activated' bonds. The initial uptake of periodate was, however, erratic and invariably in excess of the total ribose content. In some samples even the increment in consumption of periodate resulting from mild alkaline hydrolysis was greater than the total ribose in the sample. As purification proceeded, the correlation improved, but only after numerous procedures were the results observed from some fractions consistent with ribose being the only moiety oxidized by periodate. These results indicated the desirability of characterizing further components of the mixture, in particular a 2'- or 3'-ribose ester. One such class of compounds might be expected with a free 5'-phosphate group. These would be relatively acidic and were therefore sought in that small proportion of nucleotide-peptide concentrate which was retained by 'Dowex-1' (formate) in the presence of 0.1 M sodium acetate buffer, pH 5 (ref. 10), a fraction hitherto not investigated in detail.

Elution of the 'Dowex-1' (formate) column with 0.1 N formic acid and subsequent rechromatography of poorly resolved regions on the same resin gave rise to thirteen distinct fractions. Each of these separated into two to four further fractions when passed through 'Sephadex G-25'. Certain of the latter, which absorbed ultra-violet light, reacted with ninhydrin and exhibited an increased ability to reduce periodate after mild treatment with alkali, were

* Present address: Research Laboratories, Brooke Bond Tea, Ltd., Blounts Court, Sonning Common, Reading, Berkshire.

lected for detailed examination. One such investigation described in some detail as illustrative of the results obtained.

The sample had λ_{\max} 255 m μ , λ_{\min} 235 m μ and appeared as a single ninhydrin-positive spot with coincident absorption of ultra-violet light on thin-layer chromatography on cellulose in three solvents (0.1 N hydrochloric acid, solvent *a*; propan-2-ol-water, 7:3 v/v, solvent *b*; saturated ammonium sulphate-0.1 M sodium acetate H 7.5-propan-2-ol, 40:9:1 v/v). It failed to move or separate on paper electrophoresis (0.1 M sodium acetate buffer, pH 4, 36 V/cm). After treatment at pH 10 for 16 h at room temperature it was possible to separate the ninhydrin positive and ultra-violet absorbing material by paper chromatography (solvent *b*).

The peptide moiety was eluted and purified by paper electrophoresis and chromatography before being hydrolysed (6 N hydrochloric acid, 100°, 16 h, sealed tube). Amino-acids, determined by the method of Spackman, Stein and Moore¹⁸, were present in the hydrolysate in the approximate ratio glutamic acid:glycine:serine:alanine, 2:1:1 (Table 1) together with traces of aspartic acid, threonine and lysine. Reaction of the original material with 'dansyl' chloride²⁰ and subsequent hydrolysis yielded a single derivative tentatively identified as dansyl-alanine by chromatography²¹.

Table 1. ANALYTICAL DATA ON A SELECTED NUCLEOTIDE PEPTIDE FRACTION

	Moles/mole ribose
Nucleotide (calculated as G)	1.2
Periodate consumed: (a) Initially	0.9
(b) After hydrolysis at pH 10	1.03
That is, ribose-ester bonds	0.13
Amino-acids: Glu	0.063
Gly	0.05
Ser	0.026
Ala	0.022
That is, total peptide	c. 0.024

The nucleotide moiety was also subjected to hydrolysis (0.3 N potassium hydroxide, 37°, 16 h) after elution from the paper. Paper chromatography of the products (*n*-butanol-acetic acid-water; 4:1:1 v/v) revealed two components (*A* and *B*, $R_F = 0.2$ and 0.38 respectively) with distinctive ultra-violet absorption spectra (Table 2). Neither component could be identified when compared with all the available authentic bases or nucleoside monophosphates either by paper or thin-layer chromatography or by electrophoresis. Component *A* was then subjected to acid hydrolysis (pH 2, 100°, 10 min) and the products chromatographed on paper (*n*-propanol-ethyl acetate-water, 7:1:2 v/v) adjacent to unhydrolysed component *A*. On developing with silver nitrate it was apparent that a hexose had been released by acid hydrolysis. This was identified as galactose, together with traces of glucose and mannose, by paper chromatography (pyridine-ethyl acetate-water, 4:10:3 v/v, and methyl ethyl ketone-acetic acid-water, 9:1:1 v/v saturated with boric acid) and electrophoresis (0.1 M sodium borate buffer, pH 10, 22 V/cm). Finally, the nucleotide remaining

after acid hydrolysis was tentatively identified as guanosine 5'-phosphate by eluting from chromatograms of the hydrolysate and re-running on paper (propan-2-ol-6 N hydrochloric acid, 17:8 v/v; solvent *c*). Similar treatment of component *B* failed to reveal any acid-labile carbohydrate. The spectral characteristics and chromatographic behaviour (Table 2) of this component therefore suggested that it was a methylated guanosine²².

From the data enumerated so far, it is tempting to suggest a structure for this nucleotide peptide such as:

Galactose-pGpMeG-peptide

Indeed, a rather similar glucose-cytidylic acid-peptide having a qualitatively identical amino-acid composition has recently been isolated from chlamydospores of oat smut²³. The quantitative data collected in Table 1 are, however, not in agreement with such a conclusion. One might reasonably expect to recover at least 20-30 per cent of the peptide after eluting and re-running several times on paper. In this event there is reasonable agreement between the amounts of peptide and material which reduces periodate released by cleavage at pH 10. There is, however, far too little of either ribose-ester bonds or peptide when compared with the total nucleotide content. Furthermore, phosphate analyses were not in accord with this view. Perhaps the best interpretation is that the fraction is a nucleotide derivative of galactose some 5-10 per cent of which bears a peptide attached by a ribose-ester bond.

It is clear that neither the techniques of separation nor the criteria of homogeneity so far used have been adequate. Thus the possibility that the fraction may be considerably more complex cannot be entirely excluded in view of the known strong association of guanine derivatives²⁴ and the recently reported occurrence of xanthosine monophosphate galactose in close association with nucleotide peptides from *Escherichia coli*¹².

Several other apparently homogeneous ester-linked components were also examined in detail, but in no case were satisfactory quantitative data obtained to support the qualitative findings. In addition, several other fractions from the 'Sephadex' columns which were clearly heterogeneous were fractionated further on DEAE-cellulose according to Tomlinson and Tener²⁵. Invariably, in addition to fractions exhibiting typical nucleotide spectra, several other components were obtained with λ_{\max} 225-230 m μ ; 321 m μ , λ_{\min} 267 (pH 2 and 7), and λ_{\max} 232-233 m μ ; 308-310 m μ , λ_{\min} 264 (pH 9). These latter were not investigated closely, but it was established that they reduced periodate very rapidly. Compounds with these spectral characteristics were also found in considerable amounts in the whole nucleotide-peptide concentrates.

The presence of bound hexoses and materials which react readily with periodate, other than the nucleotide peptides themselves, invalidates the measurement¹⁵ of the proportions of anhydride and ester-linked compounds in these nucleotide peptide concentrates. Thus, the reported changes in these compounds accompanying physiological changes in the cells^{14,23-28} cannot be regarded as having any quantitative significance or affording any indication as to the metabolic significance of nucleotide peptides.

One class of nucleotide peptides having ribose-ester bonds might arise by the action of ribonuclease on ribosomal-bound transfer-RNA peptides^{3,29} during the extraction procedure or, in cell-free systems at least, by degradation of the transfer-RNA-amino-acid prior to peptide bond formation, a process which inhibits protein synthesis and presumably releases nucleotide peptides³⁰. The nucleotide composition of such components should reflect the characteristic terminal sequence of transfer-RNA. Such products would not be intermediates in protein synthesis but might provide an explanation of the apparent connexion between nucleotide peptides and protein synthesis³¹⁻³⁴. Although investigations of the

incorporation of radioactive amino-acids into protein by systems derived from yeast and dependent on either ribosomes³⁵ or a heavier particulate fraction³² have indicated that this incorporation is accompanied by passage of radioactivity into materials which possess the characteristics of nucleotide peptides^{32,34}, kinetic evidence has failed to demonstrate an intermediary role for these substances in protein synthesis in either system³⁴. From the extract of the heavier particulate fraction the nucleotides obtained by alkaline degradation may well have been characteristic of terminal fragments of transfer-RNA³². However, it has not proved possible to isolate, from either system, sufficient radioactive material in an adequate state of purity to elucidate the nature of the bond between nucleotide and peptide³⁴. No nucleotide peptides having structures compatible with terminal fragments of transfer-RNA have, as yet, been adequately characterized and, to judge from the overall nucleotide composition of the preparations^{1,11}, it seems likely that only a relatively small fraction could be so derived. Perhaps the most reasonable explanation of an apparent intermediary role in protein synthesis in living cells³³, which is unconfirmed in cell-free systems, is that certain nucleotide peptides are involved in the elaboration of structures which require the integrity of the cell, such as membrane, mitochondria, or cell walls²⁸.

Although fragments of transfer-RNA amino-acid derivatives inhibit protein synthesis³⁰, it is not obvious that the analogous peptide derivative could have the similar but apparently specific action required to explain the repression of the induced synthesis of α -glucosidase observed by Koningsberger *et al.*³⁶. We have also examined the latter phenomenon using a strain of *Saccharomyces cerevisiae* (National Collection of Yeast Cultures No. 366). Cells in early log phase and protoplasts derived therefrom showed an induction pattern almost identical with that of stationary phase cells of this strain³⁷. Initially, in the presence of rather crude preparations containing nucleotide peptides our observations were very similar to those of Koningsberger *et al.*³⁶. Attempts to fractionate these preparations by the techniques already outlined here, however, afforded rather confusing results, several fractions exhibiting similar activity being obtained. Repeated passage through 'Sephadex G-25' and final removal of traces of salts on ion retardation resin ('Bio-Rad. AG11A8') led to a gradual loss in activity, suggesting either that the active material is rather labile or that it is not, in fact, nucleotide peptide. One of the most surprising observations was that one fraction which had been kept cold throughout the preparative manipulations and exhibited only very slight activity was able to inhibit completely the synthesis of maltase in protoplasts after it had been warmed at 60° for 10 min.

We also have independent evidence that may indicate the presence of substances having repressor-like activity in the readily extractable pool of low-molecular-weight substances from yeast. The sequential induction of the components of the maltose utilizing system in a further strain of *Saccharomyces cerevisiae* (N.C.Y.C. 240 M), in which maltase activity only became apparent some 3.5 h after the addition of the inducer, was described earlier³⁷. It has since been found that this behaviour is dependent on the temperature at which the cells are washed prior to addition of the inducer. The delayed induction, in fact, occurs only after the cells have been washed at 0°–5°, whereas washing at 20–25° results in induction within less than 2 h. The latter effect can, however, be largely offset by an increase in the concentration of glucose in the inducing medium. One possible explanation is that washing at the higher temperature removes substances with repressor-like activity. Freeze-dried washings are, however, without effect on the induction in whole cells or protoplasts when observed manometrically. Nevertheless, it is possible that the repressor is degraded on excretion by enzymes located in the cell wall³⁸. Indeed, this could

also explain the observation³⁶ that repressor activity can be demonstrated on protoplasts but not on whole cells. These observations may, perhaps, be connected with the phenomenon of shock excretion of amino-acids as nucleotides³⁹ which is enhanced by elevated temperature. Conceivably, some of the excretion products may be derived from nucleotide peptides; indeed, it is not impossible that one function of shock excretion is removal of repressor substances prior to an adjustment of enzyme levels in response to a change of environment. Again these ideas, however, radioactivity from nucleotide peptides obtained from yeast grown in the presence of radioactive amino-acids failed to enter either cells or protoplasts to any significant degree⁴⁰, and a synthetic nucleotide peptide⁴⁰ linked by a 5'-phosphoanhydride bond failed to support yeast growth despite the fact that the tetrapeptide moiety alone was able to serve as a nitrogen source⁴¹.

The precise significance of these results remains uncertain. There seems little doubt that low-molecular-weight substances having a repressor-like activity exist in yeast, but whether this observation is distinct from that of catabolic repression and is more specifically associated with nucleotide peptides seems rather doubtful. The variety of structures which have been observed make it unlikely that one can assign a single function to nucleotide peptides. Some may fulfil a genuine intermediary role in the assembly of cellular structures. The picture is a complex one and, for further systematic study, require the application of additional separation techniques and the development of more rigid criteria of homogeneity.

We thank Dr. A. H. Cook for his advice.

A MOLECULAR MODEL FOR A SODIUM PUMP

By DR. L. J. OPIT and DR. J. S. CHARNOCK

Cell Physiology Research Unit, Department of Surgery, Queen Elizabeth Hospital, Woodville, South Australia

ALTHOUGH there are considerable experimental data relating to the exclusion of Na^+ and accumulation of K^+ in living cells, our knowledge of the mechanism is rudimentary and the molecular basis for this phenomenon remains unknown. Excellent reviews^{1,2} stressing these deficiencies continue to be published. From the work of Skou, Post, Glynn and Whittam during 1957-61 there is strong evidence that the enzyme system known as Na^+ and K^+ dependent adenosine triphosphatase is closely associated with the active transport of sodium and potassium ions across cellular membranes.

In summary, the salient characteristics which relate this enzyme system to the movement of Na^+ and K^+ are:

(1) The enzyme system is membrane bound, and virtually ubiquitous in animal cells^{3,5,7}.

(2) It requires the presence of both Na^+ and K^+ ions for activation—a well-known requirement for ion transport in whole cell or tissue systems *in vitro*⁶⁻⁸.

(3) In the erythrocyte, enzyme activation occurs only when Na^+ is on the 'inside' and K^+ is on the 'outside' of the cell^{9,10}.

(4) Na^+ and K^+ activated ATPase is specifically inhibited by the cardiac glycoside ouabain, known to be a potent inhibitor of cation transport both *in vivo* and *in vitro*^{9,7,11}.

(5) Kinetic examination of the reaction *in vitro* shows activation by substrate and ions, and inhibition by ouabain at concentrations compatible with 'physiological conditions'^{7,12}.

Studies by Charnock and Post^{13,14}, Rose¹⁵ and others^{1,16} have suggested the following reaction mechanism for the hydrolysis of ATP by this enzyme in the presence of Mg^{++} , Na^+ and K^+ :

The initial reaction step consists of the rapid reversible formation of a phosphorylated complex. This step is stimulated by Na^+ ions, and no other ion appears able to replace Na^+ . The formation of this complex is followed by an almost irreversible decomposition to P_i and free enzyme. This latter reaction is stimulated by K^+ but not Na^+ ions; K^+ can be replaced with either NH_4^+ , Li^+ , Rb^+ or Cs^+ . It is this decomposition which is inhibited by the cardiac glycoside ouabain. The chemical nature of the phosphorylated complex is not yet known, although it seems certain that it is phosphoprotein and not phospholipid¹³⁻¹⁷. Kinetic data from this laboratory also support this general reaction mechanism. The K_m for ATP is 2.8 mM; ADP acts as an inhibitor. Little consistent inhibition is apparent with concentrations of phosphate as high as 30 mM (ref. 12).

Although the details of the reaction mechanism of this membrane-bound ATPase have been extensively studied, the means by which this enzyme effects a vectorial transport of Na^+ and K^+ is unknown. Further advances in understanding the mechanism of Na^+ and K^+ transport

therefore require information about how such an ATPase might transport Na^+ against the concentration gradient from the inside of the cell, coupled with the movement of K^+ in the opposite direction. The purpose of this article is to present a molecular model for the directional transport of these ions based on what is known of the ATPase reaction mechanism, and which is consistent with knowledge about Na^+ and K^+ transport characteristics in the whole cell or tissue.

It has been generally accepted that the ATPase enzyme itself is membrane bound. We have recently obtained evidence that the enzyme preparation obtained from guinea-pig kidney cortex consists entirely of bilaminar membrane structures, many of which are vesicular, and which are thought to be derived from the endoplasmic reticulum of the kidney cells¹⁸.

We propose, therefore, to develop the model on the basis of these bilaminar membrane fragments and take as our starting point the configuration of the unit membrane proposed by Danielli. This unit contains a double protein layer, with lipid interposed. We will consider the inner facing protein structure to contain the ATPase enzyme. This belief is supported by the observations of Whittam that hydrolysis of ATP only occurs in the red cell ghost when the ATP is intracellular¹⁰.

If, in the intact cell, these enzyme membrane fragments were associated with cell surface or its prolongations into the cell and the endoplasmic reticulum¹⁹⁻²¹, then it is reasonable to suppose that the outer protein surface is directed toward the extracellular compartment.

The inner protein structure containing the ATPase must now be visualized as a highly ordered, polarizable chain, with many surface orientated cationic and anionic groups. Among the groups are situated a much smaller number of amino-acid groups that constitute the active centre of the ATPase enzyme itself (Fig. 1). The justification for this type of approach to biologically active protein structure has been developed in some detail by Ling²², who refers to the active centre as the cardinal site.

In the first state of the protein enzyme which we will consider, the model presupposes that the fixed anionic sites will show no strong preference for either Na^+ ions or K^+ ions, but will form associated ion pairs with either ion. The proportion of ion pairs formed by Na^+ will depend on the Na^+ concentration relative to the K^+ concentration. To initiate operation of the 'sodium pump' a critical number of the protein anionic sites must be occupied by sodium ion pairs. Thus we propose to start with the concept that the operation of the 'pumping cycle' has an inherent feed-back control. The enzyme cycle is stimulated by raising Na^+ concentration and depressed as this concentration falls and the K^+ concentration rises. As a result of sufficient sodium ion pair formation, there is a redistribution of electron density throughout the macro-molecule, and this occurs as a result of both direct and indirect interaction between Na^+ and the protein.

As in the protein fixed-charge model developed by Ling²², it is considered that the short-range interactions predominate in importance, and contribute in particular to the difference between the sodium and potassium

protein ion pairs. The inductive effect of the cation on the fixed-charge system will be additive and hence the effect of the sodium ion will bear a relation to the number of fixed anionic sites occupied by sodium ions.

Because the protein will also contain surface orientated cationic groups it will also form associated ion pairs with anions at these sites. The interaction between anion and the protein will also effect the induction of charge by cation-anionic site ion pairs. Thus when sodium and potassium are present as fluoride salts *in vitro* the ATPase activity is virtually abolished¹². In this model we imply that the highly electro-negative fluoride anion is capable of preventing the inductive changes produced by Na⁺ adsorption and which are necessary to initiate operation of the enzyme.

The redistribution of electron density induced by sodium ion pair formation is focused in the neighbourhood of the cardinal sites, and, as a result, this centre now reacts more actively with the substrate (ATP) to form the phosphorylated intermediate (Fig. 1). This step corresponds to the biochemical reaction sequence:

As a result of the phosphorylation of the cardinal site, there is a further inductive effect, and a redistribution of electron density along the polarizable chain of the protein. This produces a folding or deformation of the protein as well as a change in the adsorption energy of the fixed anionic site.

The deformation of the enzyme results, in the model, in a rotation outwards of many of the fixed anionic sites, but

leaves the phosphorylated site 'anchored' and still inward facing (Fig. 2). There are many ways in which the deformation might produce such a change in orientation of the molecule. We consider there is evidence for believing that the whole membrane structure is concerned in the transport process, although not directly part of the enzyme.

It is interesting to note that a recent paper by Tanaka and Abood has suggested that lecithin is required to restore activity to this enzyme after treatment with deoxycholate²³. We would interpret this finding as suggesting that the lipid is a necessary part of the enzyme system, although not involved in the chemical reaction itself.

The deformation suggested, therefore, implies unfolding, or lengthening the inner enzyme protein chain with subsequent rotation of the membrane fragment about the central lipid core. For a membrane unit of 1000 Å long and 60 Å wide, and assuming that the axis of rotation is in the centre of the lipid core, a change in length of about 50 Å would be required to produce a single 27° spiral.

Because of the adsorption energy changes associated with this phosphorylation and subsequent enzyme deformation, a marked preference for K⁺ is now exhibited by the cation binding groups, and the Na⁺ at these sites is exchanged for K⁺ (Fig. 2). The previous rotation of the membrane now implies that this exchange occurs extracellularly, hence Na⁺ has been transported from the intracellular to the extracellular environment. The adsorption of K⁺ on to these sites while the macro molecule is in this state of 'electron strain' again redistributes the electron density. In the region of the

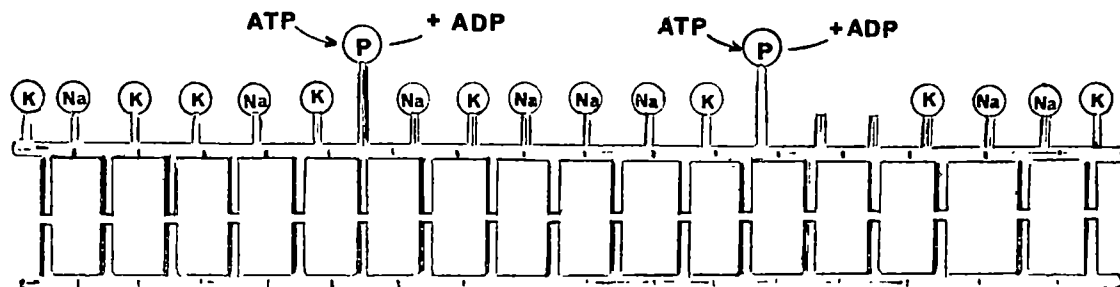

Fig. 1. Diagrammatic representation of a unit segment of membrane in which the horizontal sections depict the inner and outer protein layers, and the vertical broken units between the protein represent the central phospholipid complex described by Danielli. Projecting from the inner coil are shown the surface orientated anionic groups of the protein with which Na⁺ and K⁺ have formed associated ion pairs. The longer vertical projections represent the amino-acid groups which constitute the active centre of the enzyme. In this figure sufficient sodium ion pairs are considered to have formed to allow the active centre to react with ATP, and form the phosphorylated intermediate. Although the figure shows ATP reacting directly at the cardinal site it has long been established that magnesium ions are required for this reaction Mg²⁺ has been omitted from the figure for clarity.

Fig. 2. Representation of the postulated effects of phosphorylation of the active centre of the enzyme. Elongation of the inner protein surface has produced rotation of these protein molecules about the centre of the lipid core. The site of the phosphorylated active centre is shown as resisting this rotation. The surface orientated anionic groups with their associated ions have rotated outwards following the elongation and twisting of the protein molecule. K⁺ for Na⁺ exchange is now shown to be taking place at sites of Na⁺ adsorption to these groups.

Fig. 3. Diagram showing that, following the K^+ for Na^+ exchange illustrated in Fig. 2, the inductive changes of electron density which take place in the elongated protein molecule lead to changes of field strength in the region of the phosphorylated active centre. As a result of these changes the phosphorylated centre is now readily attacked by water with cleavage of phosphate from the protein.

ardinal sites this alteration in electron distribution renders the phosphate groups more vulnerable to attack by water and cleavage of the phosphate bond occurs with the liberation of orthophosphate.

The liberation of phosphate from the phosphoprotein allows the molecule to return to its initial shape, and as a result the anionic binding sites with their adsorbed K^+ state inwards toward the cell centre. Within the cell some of these adsorbed K^+ ions are now displaced by Na^+ and the cycle of reaction begins again.

These last hypothetical steps correspond with the second step of enzyme reaction sequence:

Thus the cycle results in net transfer of Na^+ from inside the cell to the outside, coupled with the transport of K^+ in the opposite direction, during which process ATP is hydrolysed to ADP and orthophosphate.

Because there is evidence that the site of ouabain inhibition is at reaction (2) in the sequence given above¹³, it seems unlikely that ouabain acts directly at the active centre of the ATPase enzyme. Ouabain does not prevent the formation of the phosphoprotein intermediate but appears to prevent its decomposition^{13,14}.

For the toxicity and action of cardiac glycosides on ion transport certain features of cardiac glycoside molecule appear essential^{24,25}. These features include a *cis*-configuration of the *C-D* ring function, the presence of a β -hydroxy group at C_{14} and an unsaturated lactone ring at C_{17} . A conformational representation of ouabain is shown in Fig. 4. Although the orientation of the molecule

will depend on the positions adopted by the lactone ring at C_{17} and the sugar moiety at C_3 , as both groups are free to rotate, a conformation could exist where the ketone group and the β -hydroxyl at C_{14} face away from the same surface of the ouabain molecule. When oriented in this position, these groups might form by hydrogen-bonding the primary attachment of the ouabain molecule to the surface of the ATPase enzyme.

In addition, a cluster of OH groups exist both on the AB rings of the aglycone and on the sugar moiety of ouabain. These groups could also form hydrogen-bonds with the protein enzyme surface. Attachment of ouabain to the protein enzyme by the separated clusters of OH-groups would act, in the model presented in this paper, by maintaining the deformed state of the membrane shown in Figs. 2 and 3. This interaction would prevent both release of phosphate from the active centre, and operation of the deformation-restoration cycle required to move Na^+ and K^+ ions in the directions required.

In the absence of direct experimental evidence, such an explanation for the mechanism of ouabain inhibition must remain entirely speculative.

The model presented in this article is an attempt to combine data about the ' Na^+ + K^+ activated ATPase' into a consistent model which seeks to explain the means by which such an enzyme could produce vectorial Na^+ and K^+ transport.

A useful model should be fragile, and ought to suggest the appropriate tests as to its own validity. We believe this model suggests at least two general questions about ' Na^+ + K^+ activated ATPase' with respect to its capacity to transport these ions.

First, Do transition states of the enzyme exist with selective Na^+ or K^+ binding capacity? The model, in fact, suggests that selective E^+ binding occurs when the enzyme is in the phosphorylated state (Fig. 3). Recently an answer to this question has been sought using a histochemical electron microscope technique. With this we have been able to show what is believed to be evidence of markedly increased Cs^+ binding by the enzyme membrane during the existence of the phosphoprotein transition state¹⁶. Because Cs^+ can replace K^+ completely in the enzyme reaction^{2,6} we believe that this implies that K^+ binding will occur under the experimental conditions that demonstrated Cs^+ binding. As Cs^+ has a greater electron density than K^+ it is consequently easier to visualize using the electron microscope.

This evidence has necessitated the inclusion of a further step in the reaction sequence to account for a potassium exchange.

Fig. 4. Conformational representation of ouabain (3-O- β -D-rhamno-pyranosyl-1,3,3,5,11a,14,19-hexahydroxy-5 β -cardo-20(22)-enolide). We are indebted to Dr J. Mills, C S I R.O. Division of Biochemistry and General Nutrition, Adelaide, for this interpretation of the structure. Rotation of the rhamnose molecule will produce a configuration in which the undersurface of the molecule is hydrophobic, and the upper surface contains projecting OH and =O groups. We envisage that these groups form hydrogen bonds with the extended surface of the inner membrane protein containing the ATPase.

A second question which the model poses is: Does a measurable or detectable degree of molecular deformation occur during or following the formation of the phosphoprotein? One approach to the solution of this question requires direct biophysical examination by such techniques as X-ray diffraction, flow birefringence or light scattering. We have recently been able to show that the particulate enzyme gives a clear orientated X-ray diffraction pattern although as yet we have obtained insufficient resolution to determine the presence of significant deformation²⁶.

A more indirect approach would be to attempt an estimate of entropy change associated with the hydrolysis of ATP by this enzyme. The model predicts that the entropy values should be high for the ouabain-sensitive Na⁺ and K⁺ ATPase, and much less for the ouabain-insensitive ATPase which is always associated with our preparations.

Other workers interested in 'Na⁺ + K⁺ activated ATPase' have speculated about the mechanism of ion transport by this enzyme. Some authors have considered that either ATP itself, or the phosphate group of the labile phosphoprotein, acts directly as the ion carrier²⁷. However, most investigators have treated the enzyme as a polyanionic macromolecule the ion selectivity of which is determined by the turnover of labile phosphate groups^{1,2}. Eisenmann²⁸ has evolved characteristics for such a selective ion binding system which is based on the field strength of the anionic site, and Ling²² has developed this type of approach with considerable rigour as the basis of specialized protein function in general.

Working with the 'Na⁺ + K⁺ activated ATPase' from the electric organ of the electrophorus, Albers, Fahn and Koval²⁹ have suggested a model with spatial separation of three enzyme steps. Their model, however, suggests that Na⁺ and K⁺ movement is coupled with the translocation of phosphate from inside the cell, but fails to account, however, for the return of the phosphate to the cell.

All these models have sought to explain the changing selectivity of binding sites associated with the enzyme

'ion carriers', but none of them has attempted to include an explanation of the vectorial nature of the ion movement, or the highly selective inhibition of both the enzyme and ion transport by the cardiac glycosides. Although the model presented in this article will undoubtedly be proved to be inconsistent as new facts emerge, we believe that it will help to suggest the experiments necessary to uncover these new facts.

Relictogobius kryzhanovskii AND THE PENETRATION OF MEDITERRANEAN GOBIES INTO THE BLACK SEA

By DR. P. J. MILLER

Department of Zoology, University of Glasgow

THE Ponto-Caspian seas of southern Russia are of particular interest to the European ichthyologist in their diverse fauna, with its endemic components, and its relationships to that of the Mediterranean. In addition, nomenclatural problems involving Mediterranean species have resulted from systematic work on this fauna. Fortunately, detailed reviews of both the hydrography and zoogeography of the Black and Caspian Seas have recently become available in English¹⁻³ together with several comprehensive lists of the fishes of these seas⁴⁻⁶. Both seas, and their tributary drainage systems, are populated in varying part by endemic 'Caspian' (= 'Sarmatic' auctt.) faunal elements of more or less stenohaline brackish-water or freshwater animals. The phyletic ancestors of these species evolved from ancient Mediterranean stock with onset of brackish conditions in the vast Sarmatic basin of the South Russian geosyncline

after this had become separated in the Upper Miocene from the Mediterranean region of the disappearing Tethys Sea. The establishment of the present connexion between the Black Sea and Mediterranean in the late Pleistocene (post-Würmian^{3,7}) led to an increase in salinity of what had previously constituted the semi-fresh Novo-Euxine stage in the history of the Black Sea basin. In consequence, the originally widespread Caspian fauna of the latter now survives as ecological relicts in environments of lower salinity provided by coastal lagoons ('limans'), estuaries of rivers, and the Sea of Azov, and has been largely replaced in coastal and open waters by Mediterranean immigrants which have entered the Black Sea probably within the past 12,000 years⁷. Although there are many Caspian forms restricted in distribution to the Caspian Sea, the existing Caspian fauna of the Black Sea exhibits little endemism above the subspecific level,

wer than 5 per cent of the species being absent from the Caspian Sea. This has been attributed to the effect of an earlier Pleistocene (Early Würm/Main interstadial¹, or Riss/Würm interglacial²) ingress of Mediterranean waters into the Black Sea basin, when the Caspian fauna of the then hyposaline Ancient Euxine stage of this basin is believed to have been almost completely eliminated from the ensuing marine Karangat era³. After the closure of this connexion with the onset of the main Würmian glaciation^{4,5}, salinity of the Black Sea basin became once more reduced and a Caspian fauna, mostly identical in species with the present one, was re-established throughout the sea by immigration from that persisting in the previously isolated basin of the Caspian Khvalynsk stage (via a temporary river, flowing westward, along the Manych depression)³.

In the modern Black Sea, gobiid fishes form significant elements in both the Caspian and Mediterranean components of the fauna⁴⁻⁶. Among those at present included in the former is the monotypic genus *Relictogobius* Pchelina⁸, represented by *R. kryzhanovskii* Pchelina, known from the type locality, a saline lagoon (20 ‰), closely walled off from the sea, on the Abrau Peninsula, near Novorossiysk, U.S.S.R. (44° 42' N., 37° 45' E.)⁸, as well as from Sochi, to the south-east (43° 35' N., 39° 40' E.)¹⁰, and from the Gulf of Varna, on the Bulgarian coast (43° 13' N., 27° 55' E.)⁹. *Relictogobius* has recently been listed as the only non-freshwater fish genus endemic to the Black Sea⁸. This is in marked contrast to the other 'Caspian' Black Sea gobiids which occur also in the Caspian basin and the populations of which found in the two regions are differentiated into no more than sub-species^{3,10}. The Caspian Sea also contains several bizarre genera and species of gobiid fishes lacking in the Black Sea¹⁰. Had the existence of *Relictogobius* not been apparently overlooked, its level of differentiation suggested by generic status could have provided evidence for persistence through the marine Karangat era of Ancient Euxine forms the survival of which into the Novo-Euxine phase has been the subject of controversy^{2,3}.

However, while compiling a check-list of European gobies (unpublished), I was impressed by the similarity between published illustrations^{8,9} of *R. kryzhanovskii* and specimens of the widely distributed Mediterranean *Gobius quadrivittatus* Steindachner, hitherto unrecorded from the Black Sea. Although the type specimens of the former were destroyed at Novorossiysk during the Second World War¹¹, the original detailed account leaves no doubt that the two species are identical. Both are small (up to 65.5 mm), elongate gobiids, with about 60-70 rows of cycloid scales in lateral series, a tubular posterior nostril, naked nape and breast, canine teeth, no free pectoral fin-rays, and in coloration show an intricate pattern of dark vermiculate markings over the head, numerous vertical bars across the flanks, and three pale transverse bands across the back, the broadest and most conspicuously demarcated being across the posterior nape and pectoral bases. The modified lateral-line system on the head lacks the cephalic canal ρ^1 - ρ^2 (nomenclature of Sanzo¹²), but shows a seventh transverse sub-orbital row of sensory papillae, extension of the most posterior inferior segment of the sub-orbital series towards preopercular-mandibular row e, and approach or union in dorsal midline of occipital rows o. *Gobius quadrivittatus* was made the type of a new sub-genus (*Chromogobius*) of *Gobius* L. by De Buen¹³. Suitably expanded in definition to include another Mediterranean form (identified by me as *Gobius depressus* var. *zebrata* Kolombatovic), this taxon could well rank as a separate genus, for which *Relictogobius* Pchelina 1939 becomes a junior subjective synonym of *Chromogobius* De Buen 1930.

Chromogobius quadrivittatus thus joins the increasing list of Mediterranean gobiids recognized as having penetrated into the Black Sea. These also now include *Gobius niger*

L., *G. paganellus* L., *G. cobitis* Pallas (= *G. capito* C. & V.), *G. buccichi* Steinbachner, *G. ophioccephalus* Pallas, *Pomatoschistus minutus elongatus* (Canestrini), *P. leopardinus* (Nordmann) [*P. microps leopardinus* auct., but specifically distinct from the true *P. microps* (Krøyer)], and *Aphia minuta* (Risso)^{4,5,10,14}. All these species have in common an inshore habitat, several are known to tolerate brackish conditions, and all are widely distributed throughout the Mediterranean, with five out of nine extending outside the Mediterranean into the colder Atlantic Boreal region. In their euryhalinity and eurythermality (to be inferred from their wide geographical range), these gobies, when opportunity arose for colonization, would have been pre-adapted for life in the present Black Sea, with its broad temperature fluctuations in shallow waters and markedly lower salinity than is found in neighbouring parts of the Mediterranean². In common with most of the other Mediterranean fishes which have permanently established themselves in the Black Sea, the gobies have not formed sub-species peculiar to the latter area, although local differentiation in the case of *Pomatoschistus leopardinus* is reported from the hypersaline lakes (41.8-44.3 ‰) at Eforia on the coast of Romania¹⁵. The presumably more stenotopic offshore gobiids of the Mediterranean (such as *Lesueurigobius*, *Deltentosteus*, *Buenia*, *Odondeubenia*, *Pomatoschistus* spp., and *Cratilogobius*, etc.) have not been recorded from the Black Sea. In parts of the Black Sea comparable to their known bathymetric range (25-300 m)¹⁶, the values for temperature and salinity are appreciably less than those of the Mediterranean, and there is increasing deoxygenation and hydrogen sulphide pollution with depth^{2,17}, so that entry of these forms would seem to be effectively prevented by an array of ecological barriers. A reverse tendency for 'Caspian' gobiids to extend their range outside the Black Sea and its drainage area (including the Sea of Marmora) appears to be restricted to the brackish and freshwater *Proterorhinus marmoratus* (Pallas), found in rivers entering the northern Aegean Sea^{4,5,18}, and *Knipowitschia lencoraria* (Kessler) [= *Pomatoschistus caucasicus* (Kawrajsky) Berg], known from the mouth of the R. Yaila (Samothrace) and lagoons near Kavala, northern Greece (40° 56' N., 24° 25' E.)¹⁴. Spread of certain Caspian gobiids of Black Sea rivers into the Baltic Sea through Dnieper-Bug, Nieman, Dvina and Don-Volga-Ladoga canal connexions may also be expected^{3,18}.

I thank Dr. R. W. Hey, Geology Department, Cambridge, for advice on Ponto-Caspian successions. Useful accounts of Russian work on the biostratigraphy of Quaternary marine deposits in the Caspian, Black and Mediterranean Seas and also on the general correlation of local Quaternary sequences in Europe and the Ponto-Caspian region have recently appeared in English^{19,20}.

LETTERS TO THE EDITOR

ASTROPHYSICS

Ionosphere, and X-ray Images of the Sun

RUSSELL^{1,2} has obtained X-ray photographs of the Sun at an epoch close to the recent minimum in solar activity which occurred late in 1964 and which preceded the present rising phase of the new solar cycle. The photographs were taken from a high-altitude rocket, and the quality and resolution are sufficiently good to allow limb brightening to be clearly distinguished from several small active regions that were present on the disk. The photographs seem to suggest that, in contrast to the brightening at the limbs, there was also some darkening at the north and south poles.

These directly made photographs provide at least qualitative confirmation of the solar brightness distribution derived by me³ from ionospheric observations made during the previous solar minimum in 1954. This distribution was based on measurements of the changes in electron density, in the ionosphere, that were caused by the total solar eclipse of June 30, 1954. On the day of the eclipse, the Sun was exceptionally quiet and no active area of any importance was visible on the disk. Analysis of the ionospheric data led to the conclusion that, on this occasion, 82 per cent of the radiation could be attributed to an extended source which covered the entire disk and which was uniformly bright except for some darkening near the north and south poles. The remaining radiation (18 per cent) was attributed to limb brightening, although the slight asymmetry which was observed suggests that there may have been a very small active area near the west limb.

When ionospheric data are used to determine the brightness of the limbs relative to the uniform background, the degree of brightness which results depends on the value assumed for the effective recombination coefficient, α' , in the expression:

$$J(t) = \left[\frac{1}{\alpha'} \frac{dNe}{dt} + Ne^2 \right] \sec \chi$$

where $J(t)$ is proportional to the intensity of the incident radiation, Ne is the electron density at the peak of the E or F_1 layer, and χ is the zenith angle of the Sun⁴. The accuracy of the calculated brightness distribution is limited mainly by the uncertainty in the value of α' .

It seems likely that the new X-ray photographs will give good quantitative information about the actual degree of limb brightening near the 1964 minimum, and it is probably reasonable to assume that the brightening during the 1954 minimum cannot have been very different. If this assumption is correct, it would be possible to use the 1954 ionospheric data, in conjunction with the 1964 value for limb brightening, in a new determination of α' . The result would be of considerable interest because the numerical value and the precise significance of α' have long been subjects for controversy.

Russell also refers to the presence of sources of X-radiation which extend outwards beyond the visible limb of the Sun, as predicted theoretically by Elwert⁵. A knowledge of the rapidity with which the intensity decreases with distance from the limb would allow estimates to be made of the amount of residual X-radiation which is present during the total phase of a solar eclipse. This information also could be used in the determination of α' from ionospheric data obtained during total eclipses, and

its use for this purpose has been discussed on previous occasions^{6,7}.

Radiation Balance of Jupiter and Saturn

It is frequently stated^{1,2} that the radiation balance of Jupiter presents a significant problem in that the temperature derived for the cloud tops ($\sim 165^\circ \text{K}$) is considerably higher than the value which would be achieved by a rapidly rotating body having Jupiter's characteristic in simple equilibrium with solar radiation ($\sim 125^\circ \text{K}$). This discrepancy has been cited as possible evidence for thermal radiation from the interior of the planet; that is it has been suggested that Jupiter might still be cooling down from an early, high-temperature phase³. The role of the atmosphere in maintaining the thermal balance has generally been disregarded since it has been assumed that the known constituents were all transparent in the wavelength region of importance (20–40 μ). The situation for Saturn is very similar; the temperatures are simply somewhat lower. A number of recent findings when considered together appear to require a revision of these ideas.

Trafton⁴ has pointed out that the pressure-induced dipole absorption of H_2 may produce significant absorption in the case of Jupiter. He finds that temperatures of the order of 147°K are not difficult to maintain by an atmospheric greenhouse effect depending only on this absorber. Owen⁵ has reviewed a number of measurements of the temperature of Jupiter and has analysed one of the methane bands in the planet's spectrum to obtain a value of $200^\circ \pm 25^\circ \text{K}$. The conclusion of this investigation was that there appeared to be strong evidence for temperatures in the range 175° – 200°K in and above the cloud layer which is envisaged as considerably more complex than a simple flat surface. It thus seems necessary to invoke another absorber if the atmosphere is to provide the necessary opacity.

The way out of this dilemma appears to be provided by some recent laboratory studies of ammonia. Walsh⁶ has obtained spectra of ammonia in the region 20–35 μ at a number of path-lengths, with the gas subjected to various degrees of pressure broadening by N_2 . A series of his tracings for an equivalent path-length of about 12 m atm. of ammonia at three different pressures of N_2 is reproduced in Fig. 1. It is evident that, even with no broadening by N_2 , the transparency in this region is very low. In Jupiter's atmosphere, of course, the temperature will be lower than the laboratory value, so the population in the higher rotational levels (which are responsible for the absorption shown in Fig. 1) will be diminished. On the other hand, the atmospheric pressure within the region of the clouds is almost certainly in excess of 76 cm mercury and, while the broadening gases will be H_2 and He instead of N_2 , the susceptibility of ammonia to pressure broadening is so great that at the expected pressures the absorption

ould lie within the range displayed by the three curves Fig. 1. Whether this will indeed be sufficient to produce a required greenhouse effect can only be demonstrated by a more careful treatment which includes the absorption of other wave-lengths. The spectrum of appropriately large amounts of methane should also be examined to see whether the band at 44μ may be a significant source of acity.

Saturn presents a rather different problem. Following Dunham⁶, it is generally assumed that Saturn's atmosphere also contains ammonia. However, recent examinations of the spectrum of this planet have failed to reveal the absorption bands of this gas⁷, and an alternative explanation for Dunham's identification of ammonia in terms of an overlapping methane band has been adduced⁸. Furthermore, a recent temperature measurement by Low⁹ of a wave-length of 10μ has led to a value of 93°K , well below the earlier results of $\sim 130^\circ\text{K}$. At 90°K , the vapor pressure of ammonia is only $10^{-4}\mu$ mercury, suggesting that its spectroscopic detection is extremely unlikely. Hence the low temperature and the absence of ammonia absorption are consistent.

It thus seems highly probable that the 93° temperature refers to some level of the atmosphere within the cloud layer, that is, the thermal radiation measured at 10μ is coming from cloud particles rather than from the ν_2 absorption band of ammonia as in the case of Jupiter. There may be some radiation from higher rotational lines of the nearest strong methane band at 7.7μ . A model of the detailed structure and composition of the cloud layer will have to await additional observations, but it seems likely that the absence of convective phenomena, given by the large latent heat of sublimation of ammonia (41 cal/g mole at 198°K) may be responsible for the greater visual uniformity of the disk of Saturn compared with that of Jupiter. While it is inevitable that clouds consisting of ammonia crystals will form at some atmospheric level, the low temperature of the upper atmosphere of Saturn also permits the deposition of methane, suggesting a possible explanation for the difference in the polarization of Jupiter and Saturn reported by Dollfus¹⁰. In this view, the atmosphere above the level of visual opacity in the case of Jupiter is charged with ammonia crystals, while in the much colder atmosphere of Saturn these are replaced by crystals of methane. The difference in the polarization of the two planets could then arise from the difference in the index of refraction of the two kinds of crystals or a difference in their mean size.

The consistency established by the low temperature and absence of ammonia in the atmosphere of Saturn has interesting implications for the foregoing argument. Saturn's atmosphere is known to contain methane and hydrogen in somewhat greater amounts than the atmosphere of Jupiter. (The increase is due to the lower level of the cloud layer in the atmosphere of Saturn.) Yet the measured temperature is very close to the radiation

equilibrium value ($\sim 90^\circ\text{K}$), and apparently refers to a region in the atmosphere very close to the visually observed cloud layer. In other words, in the absence of a detectable quantity of gaseous ammonia, a Jovian-type atmosphere does not seem to have sufficient opacity to produce a large greenhouse effect. Thus either Jupiter is, in fact, still cooling down (while Saturn is not), or it is the presence of a substantial amount of ammonia in its atmosphere which leads to the observed high temperatures. The laboratory evidence presented in Fig. 1 suggests that the latter alternative must be seriously considered before resorting to the internal heat source suggested by the former.

GEOPHYSICS

Daily Variation of Cosmic Rays

ONE of the interesting properties of cosmic radiation of intermediate energies, 1-100 GeV, is the daily variation of intensity measured at the Earth. This variation, of average amplitude $\sim 0.3-0.4$ per cent, appears largely diurnal in character although harmonic analysis reveals a semidiurnal component. The maximum intensity occurs, on the average, about 1700 L.T. although the phase can vary considerably.

An understanding of the mechanism producing the variation has increased in the past few years with the discovery of the solar wind, the development of a model of the large-scale magnetic field configuration in the inner solar system, and the use of computers to achieve detailed information about the trajectories of charged particles in the geomagnetic field. Several theories have been put forward in recent months to account for the observed anisotropy in terms of the (overtaking) streaming of the cosmic ray gas parallel to the Earth's motion around the Sun. On the other hand, Sarabhai *et al.*¹ have suggested

that part of the daily variation is due to removal of particles from the morning side of the Earth due to scattering by magnetic irregularities. This communication proposes an alternative mechanism for such removal.

Several investigators have calculated particle trajectories under the influence of the Earth's magnetic field to ascertain 'asymptotic' directions of such particles, as a function of rigidity, outside this influence. By projecting a negative particle from the Earth (re-creating the history of a positive particle arriving at the Earth) and following its trajectory until the path leaves the

Fig. 1. Absorption spectra of ammonia subjected to pressure broadening by nitrogen (ref. 5)

magnetosphere, orbit calculations have been made in detail for protons entering this region of influence of the Earth. Allowing for the energy spread of primary particles capable of contributing effectively to neutron monitor counting rates, and for atmospheric effects, protons may enter the magnetosphere within an appreciable cone of directions prior to detection on the Earth at any location. The cone will, however, be restricted to equatorial latitudes for low and middle latitude detectors.

Outside the magnetosphere, however, the magnetic field has a value of about 3 or 4γ, and is usually considered to be oriented in the basic pattern of an Archimedes spiral centred on the Sun. When the cone looks up the Archimedes spiral, most of the detected primaries will have mirrored between the Sun and the Earth, assuming that the Alfvén guiding-centre approximation is valid and ignoring magnetic irregularities in the spiral. Cosmic ray primaries approaching the Earth from the antisolar direction up the spiral will be largely isotropically distributed in direction. (We should, perhaps, emphasize that in this model the majority of particles detected at the Earth by neutron monitors are confined to the spiral arm.) Passing the Earth, those the pitch angles of which are large will mirror near the Earth and then pass outwards along the spiral. For smaller pitch angles the mirror points will be closer to the Sun. For very small pitch angles, however, the mirror points will be in the Sun and the particles will be lost. Using the subscripts E and S for values at the Earth and Sun respectively, the critical value for the pitch angle α_E is given, assuming the conservation of magnetic moment, by:

$$\frac{\sin^2 \alpha_E}{\sin^2 \alpha_S} = \frac{B_E}{B_S}$$

that is, $\sin \alpha_E = (B_E/B_S)^{1/2} \approx 5 \times 10^{-3}$ assuming $B_r \propto (\text{distance from Sun})^{-2}$, that is, $\alpha_E \approx 5 \times 10^{-3}$ rad. Assuming an isotropic pitch angle distribution at the Earth, the number of particles absorbed by the Sun will be:

$$\Delta N = \frac{N}{4\pi} \int_0^{2\pi} d\phi \int_0^{\alpha_E} \sin \theta d\theta \approx 10^{-5} N$$

where N is the number density of particles. The free space anisotropy should therefore be of the order of 0.001 per cent. Neutron monitors, however, detect primaries from restricted angle of approach. For Sulphur Mountain the effective solid angle is about 2×10^{-2} sterad. Hence the detected flux:

$$F \approx \frac{2 \times 10^{-2}}{4\pi} \cdot NV \approx 1.7 \times 10^{-3} NV$$

where V is the velocity.

Thus $\Delta F/F = \Delta N \cdot V/F \approx 0.6$ per cent when asymptotic direction of approach coincides with Sun-Earth field line. This value, however, overestimates the magnitude of the anisotropy since the particles, differing rigidities, absorbed by the Sun would not have contributed with equal effectiveness to the direct response of the detector. On the other hand, if B_r should vary more slowly than $1/r^2$, the effect will be enhanced.

The effect of the cosmic-ray gas streaming past Earth due to co-rotation of the gas with the Sun has been estimated by Axford² and Parker³ to be of the order of 0.4–0.7 per cent. The predicted minimum due to this effect is at 0600 L.T. The solar absorption effect will, however, be directed up the spiral, 45° west of the Earth-Sun line. The resultant will therefore be the vector sum of the two effects. Figs. 1a and b show the frequency occurrence of the experimentally observed anisotropies polar diagrams for 1964 for selected days at Sulphur Mountain and Calgary respectively (counting rates 10^6 and $2.5 \times 10^5/\text{h}$ respectively). Selection of the data was based only on internal consistency between the data from 154 days are included. It is clear from the plots that the minimum direction is centred on 60° west of the Earth-Sun line. The averaged amplitudes of the minimum for the data taken together are 0.56 ± 0.01 per cent and 0.56 ± 0.01 per cent for Sulphur Mountain and Calgary respectively. Both direction and magnitude of the observed minimum are in fair agreement with the vector sum of the two effects considered, taking the lower value of 0.4 per cent for the streaming mechanism.

The absorption mechanism suggested by the authors is restricted by the following considerations:

(1) The gyroradii of the participating particles must be less than the scale size of irregularities in the magnetic field. This being so, the guiding centre approximation remains valid. When the gyroradii are of the same magnitude as the irregularities, however, the particles are scattered by the latter, and the fraction that reaches the Sun will be small.

The gyroradii of protons the pitch angles of which are $\leq 5 \times 10^{-3}$ radians in a field $B_E = 4\gamma$ and the energies of which are 1, 10 and 100 GeV are less than 5.5×10^3 , 4.5×10^4 and 4.0×10^6 km respectively.

Assuming the spiral field suggested by Parker³ and the constancy of $(\sin^2 \alpha)/B$, it follows that the gyroradius of a proton decreases almost linearly with decreasing distance from the Sun. Measurements by Explorer

Fig. 1. Direction-frequency plot of T_{\max} and T_{\min} for the daily variation in neutron intensity for 154 days during 1964 at (a) Sulphur Mountain and (b) Calgary, Canada

VIII⁵ indicate periods in which magnetic irregularities 10^5 – 10^8 km exist. If 10^5 km is the minimum extent the fluctuations, then the mechanism will be operative and will be independent of energy. Should smaller irregularities occur an energy dependence would be expected.

(2) The direction of minimum intensity will be that of the field lines at any instant, and since their direction changes over periods of a few minutes to a few hours $10^5 \sim 10^7$ km 450 km/sec] there will be a broadening of the minimum and perhaps a difference in the recorded time of minimum for stations whose cones of acceptance do not greatly differ.

(3) Changes in direction of the 'average' spiral field on a day-to-day basis will be responsible for part of the spread in direction of T_{min} as observed in Figs. 1a and b. Such fluctuations would be related to changes in solar wind velocity.

Frequency Spectrum of Doppler-shifted Whistler-mode Signals

To further our knowledge of very-low-frequency signals received via the whistler mode of propagation we have constructed a 25-channel spectrum analyser. Other work^{1,2} has shown the existence of apparent Doppler shifts on these signals of up to two or three parts in 10^5 of the carrier frequency; but the equipment used did not allow the variations of doppler shift with time to be resolved to better than 30 min. It sometimes appeared that there could be large positive and negative shifts occurring within a single 30-min period.

The new equipment consists of 25 filters, of the coherent detector-low pass amplifier type, in which the filter is tuned to the reference frequency supplied to the coherent detector and the band-width is determined by the low-pass amplifier. Use of this type of circuitry reduces the problem of the alignment of a bank of closely spaced filters to one of frequency synthesis, which in this case is done electro-mechanically. One filter is at the nominal carrier frequency and the others are disposed about this, 12 above and 12 below at a nominal spacing of 2 parts in 10^5 of the carrier frequency. Each channel has a band-width of approximately 0.5 parts in 10^5 .

In the short time that the equipment has been operating whistler-mode activity has been seen fairly frequently at off-sets of several parts in 10^5 . Occasionally events such as those shown in Fig. 1 are seen in which the Doppler shifts are oscillatory in nature. This is shown more clearly in Fig. 2 where the median frequency shift is plotted as a function of time. It is probable that it was events of this nature

Fig. 2

which, when recorded on the original equipment, indicated the possibility of simultaneous positive and negative Doppler shifts.

The signals in this case are from station NPG at Seattle on a frequency of 18.6 kc/s. It will be noticed that there is a short period of 'key-up' followed by a period of 'key-down' just prior to the beginning of each hour. The loop aerial was turned to obtain a minimum of the direct or ionospheric signal, this being done to limit the spill-over of this component into the filters adjacent to the centre frequency. The large-amplitude slow-period beat on the centre channel is the result of a perfect null not being obtained. The period of the beat indicates the difference between the carrier frequency, as received, and the local standard.

GEOCHEMISTRY

Radioactive Elements in the Continental Crust

THE radioactive elements are particularly useful as indicators of the chemical composition of the deeper parts of the crust. Thorium, uranium, and potassium show a strong concentration towards the surface of the Earth and are enriched in the continental crust. The abundance of thorium, uranium and potassium can be estimated by two independent methods; a physical method based on heat-flow data, and a geochemical method based on geological premises. These estimates differ by a factor of two (Table 1). The estimates for the heat-flow data are from Clark and Ringwood¹, and are based on a 37-km-thick two-layer crust. The upper layer is 16 km thick, resting on a layer 21 km thick. Calculations

Fig. 1

Table 1. ESTIMATES OF THORIUM, URANIUM AND POTASSIUM ABUNDANCES IN REGIONS OF THE CONTINENTAL CRUST

Th (p.p.m.)	U (p.p.m.)	K (per cent)	Ref.

8.8	2.2	2.35	Clark <i>et al.</i> ³ ; median of granodiorites
5.3	1.4	1.5	1:1 ratio of mafic and felsic rocks (data from Clark <i>et al.</i> ³)
4.6	1.12	1.84	1:1 ratio of basic rocks and granodiorite (data from Clark <i>et al.</i> ³)
3.2	0.81	1.81	Estimates from heat flow
2.5	0.64	1.05	Clark and Ringwood ¹ ; surface heat flow 1.5 $\mu\text{cal}/\text{cm}^2 \text{ sec}$; average of 37 km crust
			Surface heat flow 1.2 $\mu\text{cal}/\text{cm}^2 \text{ sec}$
			Surface heat flow 1.0 $\mu\text{cal}/\text{cm}^2 \text{ sec}$

Table 2. ESTIMATES OF THORIUM, URANIUM AND POTASSIUM ABUNDANCES IN DIFFERENT REGIONS OF THE CONTINENTAL CRUST

Abundances derived from heat flow data (after Clark and Ringwood (ref. 1))	Surface heat flow ($\mu\text{cal}/\text{cm}^2 \text{ sec}$)	Depth interval (km)	U (p.p.m.)	Th (p.p.m.)	K (per cent)
Shield	1.0	0-16	1.00	4.00	1.63
		16-37	0.37	1.48	0.61
Continental	1.2	0-16	1.32	5.28	2.15
		16-37	0.42	1.68	0.69
Continental	1.5	0-16	1.87	7.48	3.05
		16-37	0.57	2.28	0.93

lations of the concentrations of thorium, uranium and potassium within each layer for different heat flows are given in Table 2. It is noteworthy that the concentrations of the radioactive elements in the 16-km layer in regions with high heat flow are comparable with the geochemical estimates made on the basis of the new abundance data by Clark *et al.*³. The concentrations calculated for the lower layer are similar to those in basalts. This could indicate that this layer has a basaltic composition. However, metamorphic processes, including generation of granite magma, and the cycling of elements within the crust could also account for the low concentrations of radioactive elements in the deep crust³⁻⁵. These processes would result in a more mafic average composition of the lower crust as compared with the higher crust³⁻⁵. There is also some indication⁶ that high-grade metamorphic rocks, especially those of granulite facies, have lower concentrations of thorium and uranium than magmatic rocks of comparable chemical composition, so that the upward concentration of thorium and uranium in the crust could be more marked than that of potassium.

Crustal abundances in general are derived from premises similar to those used to obtain the geochemical estimates of uranium and thorium in Table 1. It is possible, therefore, that we are at present overestimating many of the volatile and 'granitophile' elements in the crust, and that the average continental crust is more mafic than present estimates^{8,9}. It is worth noting that Clarke¹⁰ and Goldschmidt¹¹ restricted their estimates to the composition of a 10-mile-thick upper crust.

PHYSICS

Sub-millimetre Dispersion and Rotational Line Strengths of the Hydrogen Halides

To obtain the integrated absorption strength of narrow spectral line by direct spectrophotometric measurement high resolution is necessary and the resulting profile must be corrected for finite instrumental resolution. As an alternative, dispersion data at much lower resolution may be used to obtain line strengths, and we report some measurements on a few of the low J rotational transition in the halogen halides.

Table 1. SUB-MILLIMETRE ROTATIONAL LINE STRENGTHS IN THE HYDROGEN HALIDES

Rotational transition $J \rightarrow (J+1)$	HCl k_i (cm ⁻¹)	HCl A_i^0 (cm ⁻² atm ⁻¹)	HBr k_i (cm ⁻¹)	HBr A_i^0 (cm ⁻² atm ⁻¹)	HI k_i (cm ⁻¹)	HI A_i^0 (cm ⁻² atm ⁻¹)
0 → 1	20.88	1.73 ± 0.34	16.70	0.24 ± 0.02	—	—

We have used the method of Fourier refractometry¹ to obtain the refractive index of gaseous HCl, HBr and HI in the region 10–55 cm⁻¹ at a resolution of 2 cm⁻¹. The gases were carefully dried before introduction into the cell placed in one arm of a Michelson interferometer. Dispersive interferograms were recorded for various gas pressures up to about 500 mm mercury at temperatures near 293° K, and after Fourier transformation the difference $n(k) - \bar{n}$ between the refractive index $n(k)$ at wave number k and the mean \bar{n} over the radiation band was calculated² from:

$$n(k) - \bar{n} = \frac{1}{4\pi k t} \left\{ \arctan \frac{Q(k)}{P(k)} + \pi m \right\} \quad (1)$$

where $P(k)$ and $Q(k)$ are respectively the cosine and sine Fourier transforms of the interferogram function, m is an integer, and t is the cell length (20.3 cm). A typical set of results for HCl at three pressures is given in Fig. 1, in which the anomalous dispersion associated with the lines $J = 0 \rightarrow 1$ and $J = 1 \rightarrow 2$ is seen. The data were reduced to 760 mm mercury pressure and 300° K temperature using a standard form^{3,4}, and from these the strength per atmosphere A_i^0 of a line at wave-number k_i was calculated using the relation⁴:

$$A_i^0 = \frac{2\pi^2}{f_i(k', k'')} \left\{ n_i^2(k') - n_i^2(k'') \right\} - \sum_{j \neq i} \frac{A_j^0 f_j(k', k'')}{f_i(k', k'')} \quad (2)$$

between the refractive index difference at two wave-numbers k' , k'' ($k' < k_i < k''$) and the absorption strength. We have written:

$$f_i(k', k'') = \left\{ \frac{1}{k_i^2 - k'^2} + \frac{1}{k_i^2 - k''^2} \right\} \quad (3)$$

The experimental index values determined near any given transition k_i include the significant contributions of

Fig. 1. The sub-millimetre dispersion of gaseous HCl in the region of the $J = 0 \rightarrow 1$ and $J = 1 \rightarrow 2$ rotational lines. Each point represents the average of two independent measurements made at the pressure stated, and the curves join the experimental data points. Cell-length is 20.3 cm.

ighbouring transitions k_j and account is taken of these using the experimental refractive index data in equation (2) and including the term under the summation. The various A_j^2 , A_j^3 are found by an iterative method since they are all initially unknown. Details of the experimental method and calculation will be given elsewhere. Using our index data and some recently published values of the rotational constants⁵ to calculate the k_j in equation (2), we find the values for the line strengths given in Table 1.

CRYSTALLOGRAPHY

X-ray Studies on Highly Pure Magnesium Oxide

HIGH-PURITY (99.999 per cent) magnesium oxide was prepared by the thermal decomposition of pure magnesium oxalate dihydrate. Details of the preparation, analyses and thermal decomposition of the magnesium oxalate have been given elsewhere^{1,2}. Prior to the X-ray examination, the magnesium oxide was recrystallized by firing as a pressed disk at 1,500° C for 24 h. X-ray powder diffraction data were obtained by means of a 19 cm diameter camera using copper K_α -radiation with a nickel filter, and standard procedures. The observed spacings are given in Table 1.

CHEMISTRY

Adsorption and the Differential Capacitance of the Electrical Double-layer at Platinum/Halide Metal Interfaces

MEASUREMENTS of the differential capacitance of the electrical double-layer at an LiCl-KCl eutectic melt/platinum interface at 450° C have been made by Laitinen and Roe¹ over a range of potentials from -0.34 V to -2.11 V versus a Pt/Pt²⁺ (1 M) reference electrode. Their curve of capacitance versus potential can be roughly divided into two regions: an anodic region of comparatively high specific capacitance ($\sim 100 \mu\text{F cm}^{-2}$) and a cathodic region of low specific capacitance ($\sim 50 \mu\text{F cm}^{-2}$), the transition between them occurring at approximately -0.8 V to -1.0 V. The high values of capacitance were attributed^{1,2} to the specific adsorption of chloride ions at potentials which are presumably anodic to the point of zero charge of this interface.

Double-layer capacitance versus potential curves for other metal/melt interfaces are quite unlike the previously published curves for platinum^{1,2,4} in that they are symmetrical about a well-defined minimum at the potential of zero charge (silver, thallium and tin are exceptions to this rule in that they exhibit a step in the cathodic branch⁵). Although it appears that the halide ions are surface active, because, for example, the addition of iodide ions to a chloride melt produces an increase in double-layer capacitance⁶, the increase is the same in both the anodic and cathodic branches of the curve for a given $|e|$ (the magnitude of the rational potential).

The present work suggests that the double-layer capacitance of a platinum/melt interface is dependent on the well-known existence of oxide layers on platinum surfaces⁷, and on the specific adsorption of platinum ions at concentrations determined by the redox potential of the melt.

The capacitance of the double-layer at a flame-polished, platinum hemisphere microelectrode under certain well-defined conditions (see following) falls to a minimum at approximately -0.8 V versus a Pt/Pt²⁺ (1 M) reference electrode (Fig. 1, curve a). In the region from -0.6 V to -0.8 V the capacitance varies with time so that it is

Fig. 1. The differential double-layer capacitance at platinum microelectrode/LiCl-KCl eutectic melt interfaces at 450° C. (a) Pure melt; (b) $\sim 10^{-6}$ M Pt²⁺; (c) $\sim 10^{-5}$ M Pt²⁺; (d) pure melt

necessary to allow up to 10 min for the system to come to equilibrium at each value of potential. If this procedure is not adopted, the curve becomes less well-defined and shows a marked similarity to the curves obtained by other workers^{1,2,4}, provided that the potential is changed in a cathodic direction. If the potential is changed in an anodic direction and time is not allowed for the system to come to equilibrium, the higher values of capacitance are never attained (Fig. 1, curve *d*). Under equilibrium conditions curve (*a*) in Fig. 1 can be reproduced without any difficulty whatever the direction of potential change; provided that the potential of the platinum electrode is not taken too far into the cathodic region, where there is risk of surface modification by, for example, the deposition of alkali metal.

The slow change of capacitance with time at potentials in the range -0.6 V to -0.8 V can be attributed to the desorption of chemisorbed oxygen atoms or the cathodic stripping of a stoichiometric oxide from the platinum surface. This process is reversed as the electrode potential is returned through the -0.8 V to -0.6 V region, because of the presence of low concentrations of oxide ions even in highly purified melts in glass apparatus⁸ (purified by vacuum pre-electrolysis and filtration⁹). It is significant that the adsorption process is slower than the desorption process, reflecting not only the irreversibility of the process but also the inaccessibility of the oxide ions present at low concentration in the melt.

If the platinum surface is completely stripped over the range -0.6 V to -0.8 V, then this latter value (the point of minimum capacitance) is the zero charge potential for the system (the average value calculated from a number of experiments is -0.83 ± 0.02 V versus the Pt/Pt²⁺ (1 M) reference electrode). This value agrees rather well with the proposition that the difference between the standard electrode potential and the potential of zero charge of an M/M^{2+} couple is in the range of 0.5 V– 0.9 V¹⁰.

The addition of very small quantities of platinum ions to the melt by anodic dissolution of a platinum counter-electrode produces a number of changes in the capacitance versus potential curve (Fig. 1, curves *b* and *c*), the most interesting of which is the formation of a better defined minimum and the shift of this minimum to more cathodic

potentials. This suggests that platinum ions are adsorbed on to the electrode surface as negatively charged species perhaps as a square-planar PtCl₄²⁻ complex ion, which particularly suited to adsorption on a plane surface can lead to a more compact structure for the double-layer. The minimum capacitance in curves (*b*) and (*c*) is indeed increased over that of the pure melt even for the very lowest concentration of platinum ions and this is typical of an adsorption phenomenon. This effect could also arise from a change in the electrode surface following the electrodeposition of platinum metal. However, curve (*a*) in Fig. 2 indicates that this is not so. This curve was obtained with the previously used microelectrode introduced into a fresh melt without prior surface treatment. The minimum capacitance was reproduced within the accuracy of the method (± 3 per cent) and the addition of platinum ions (in somewhat higher concentrations than before) produced the characteristic increase at the minimum together with the cathodic shift (Fig. 2, curve *b*).

A method has been developed to make these experiments possible, the details of which are published elsewhere¹⁰. A fast rise-time (10^{-8} sec) constant current pulse is applied to the electrode system, and measurements are made of the resulting over-potential/time transient before the faradaic process interferes, that is, within 2×10^{-7} sec of the initiation of the pulse¹¹. This method¹² has been modified¹⁰ in the present work to enable measurements to be made at electrode potentials other than the equilibrium redox potential of the system. It is possible, therefore, to measure a true double-layer capacitance (free from pseudocapacitance) even in the presence of a fast electron transfer process, and hence detect the effects of the adsorption of the electroactive species.

Evidence of Thermal and Hot Processes in the 'Hot-zone' produced by Copper-64 Recoil Atoms in Solids

ALTHOUGH the mechanism of recoil atom reactions in solids has been studied by a number of authors, some important problems still remain unsolved. For example, thermal and hot processes were discriminated in the recoil atom reactions in the gaseous or liquid system¹, but this is not clear in solids. Harbottle and Sutin² have proposed a concept of chemical reactions in the 'hot-zone'; however, this concept was somewhat ambiguous from the point of view of the presence of thermal and hot processes in the 'hot-zone'. In the course of studying hot-atom chemistry of copper-64 recoil atoms in α - and β -copper phthalocyanines, we have found evidence of thermal and hot processes in the 'hot-zone' in solids.

The hot-atom chemistry of copper phthalocyanine has been investigated by Herr and Gotte³, while the effects of crystal structure on the initial retention and on the thermal annealing rate have been investigated by Cook⁴ and by ourselves⁵.

Purified α - and β -copper phthalocyanines were checked by the X-ray diffraction method. Neutron irradiation of the target materials was carried out in a nuclear reactor JIGA Mark II at Rikkyo University (neutron flux: $\times 10^{11}$ n/cm²/sec). An irradiated sample was dissolved in cooled sulphuric acid ($\sim -20^\circ\text{C}$), and the solution poured into ice water to precipitate copper phthalocyanine. Afterwards the precipitate was filtered, and the precipitate and the filtrate separately counted by means of a Baird-atomic single channel γ -ray spectrometer (crystal: aI, 1.75 in. \times 2 in.).

The relationship between the initial retention and irradiation temperature is shown in Fig. 1. To avoid any effects of thermal and radiation annealing during irradiation, all retention values have been corrected for irradiation time $t = 0$. A remarkable difference between α - and β -crystals can be seen in Fig. 1. The initial retention in β -crystals at low temperature $R_{\beta 0}$ is much higher than that of α -crystals $R_{\alpha 0}$. The shape of the curve of β -crystals is different from that of α -crystals. This sensitivity of the initial retention in β -crystals seems to be closely related to the rate of increase of the retention on annealing. Table 1 shows initial annealing rates in α - and β -crystals at various temperatures. A remarkable difference between α - and β -crystals can again be seen.

Table 1. COMPARISON OF INITIAL ANNEALING RATES IN α - AND β -CRYSTALS

Annealing temperature	Initial annealing rate α	Initial annealing rate β	α/β
87°C	0.25%	4.0%	1/16
139°C	1.0	20	1/20
198°C	3.4	50	1/15
	Mean		1/17

According to Harbottle's model², hot-zone reactions proceed in a very short time after the recoil event, and therefore they are not completed in a 'hot-zone', but continue on thermal annealing. In other words, a reaction in a 'hot-zone' will be succeeded by substantially the same kind of reaction at the recoil site on thermal annealing. If this is true, the relationship of annealing rate between α - and β -crystals must hold good for that of 'hot-zone' reactions between α - and β -crystals (at least in the thermal range of the 'hot-zone'). On this assumption, we can simply go back to 'hot-zone' reactions from thermal annealing as is shown schematically in Fig. 2(a). At the crossing-point of two lines the quantity R_h ($=5.0$ per cent) can be obtained. R_h represents reactions which complete in the 'hot-zone' and is considered to be contributed by hot processes. In this way we can estimate the percentage of thermal processes and hot processes. Fig. 2(b) shows the results obtained. The apparent insensitivity of the retention in α -crystals to temperature, and the sensitivity of the retention in β -crystals to temperature, can be easily

Fig. 1. Relationship between initial retention and irradiation temperature

Fig. 2. Estimation of thermal and hot processes in the 'hot-zone'. (a) Methods of analysis. (b) Results

understood by considering the extent of the contribution of the hot process to the retentions. This kind of analysis is limited to the polymorphic crystals in which structure-sensitive reactions are concerned at the present stage. Although this method is not very accurate (small corrective terms will be discussed elsewhere), it makes it possible to estimate thermal and hot processes which in solids it was hitherto difficult to discriminate between.

We thank Dr. Shibata for his help.

Electron Spin Resonance in X-irradiated Oriented Deoxyribonucleic Acid

SEVERAL papers dealing with electron spin resonance investigations of irradiated deoxyribonucleic acid (DNA) and its constituents have appeared in the literature¹⁻⁵. In all cases, however, unoriented powder samples have been used. In this communication we wish to report some preliminary findings made with an oriented sample of calf-thymus DNA.

Fibres of the DNA were drawn under controlled humidity conditions (66 per cent relative humidity) and wound on to a 'Spectrosil' grade quartz plate which could be mounted inside a tube⁶ of the same material, enabling the fibres to

Fig. 1. Electron spin resonance spectra of dry calf thymus DNA fibres X-irradiated at room temperature. *a*, Fibres parallel to the magnetic field; *b*, fibres normal to the magnetic field.

be irradiated in an inert atmosphere of known humidity and afterwards transferred to the electron spin resonance spectrometer. The latter was of conventional design, using 100 kc/s modulation and first derivative presentation.

Fig. 1 shows spectra obtained after irradiating the fibres (weight 10 mg) at 0 per cent relative humidity under nitrogen with 250 kV X-rays to a dose of about 1 Mrad at room temperature. Spectra are shown with the magnetic field both parallel and normal to the fibres. The spectrum for the parallel position is approximately symmetric (line width between points of maximum slope ≈ 4 gauss), while that for the normal position is somewhat broader and asymmetric. Spectra were recorded over the dose range 0–1.5 Mrad, but were in all cases similar to those of Fig. 1. After the maximum dose (1.5 Mrad) had been given, the radical concentration was estimated to be 5.6×10^{18} free spins g^{-1} corresponding to a yield $G \approx 6$ (radicals/100 eV). The radicals showed little evidence of decay over several weeks, the fibres being stored under dry nitrogen at room temperature.

It will be noticed that the spectra are very different from those obtained by Ehrenberg *et al.*³ for γ -irradiated calf-thymus DNA in two respects. First, our spectra show only a faint trace of hyperfine structure and, secondly, the line width, measured between points of maximum slope, is much less than those reported in the literature. However, when an amorphous sample of the same batch of DNA was irradiated under similar conditions, a spectrum⁷ showing a narrow central line (maximum slope width ≈ 6 gauss) and well-resolved hyperfine lines was obtained.

An attempt was made to anneal the radicals by immersing the quartz sample tube in warm water for 10 min at successively higher temperatures. Between 60° and 70° C a 50 per cent decrease in radical concentration occurred, while at 80° C there was evidence of the appearance of hyperfine lines, but these were always of low intensity.

When the tube containing the (dry) DNA fibres was opened to the atmosphere, no change in signal was observed after 30 min. The signal disappeared, however, after leaving the fibres exposed to the atmosphere overnight. It has previously been reported that the decay of radiation-produced electron spin resonance signals in DNA appears to depend on the water content³.

Since DNA is believed to have a helical structure, we consider the expected angular variation of the spectrum of a system of helically distributed radicals. Assuming that the free radical sites have the same orientation as in the undamaged helix, the g -value parallel to the helix axis will be the same for each member of a population of

repeated radical species irrespective of the helical rotation operation. With the fibre normal to the helix one has, in general, a distribution of g -values depending on the magnitudes and inclinations to the helix axis of the principal g -values of the radical species. If the g -tensor has cylindrical symmetry, a spread of g -values is, of course, obtained only if the unique direction does not coincide with the helix axis. Further consideration of the perpendicular fibre case shows that, although the spread of g -values produces an overall broadening effect, this alone will not give an asymmetric spectrum provided that the fractional change in g -value is very small.

Similar considerations apply to the hyperfine coupling tensors in that single values are split into splittings occur along the helix axis. The parallel field case is analogous to that found in single crystals when site-splittings are absent. Averaging of the spectrum occurs in the perpendicular case when one or more of the tensors exhibits anisotropy in this direction, but the spectrum becomes asymmetric only when hyperfine anisotropy is accompanied by g -value anisotropy. It can be shown, for example, that only an anisotropic doublet is present, the maximum absorption of the smeared-out spectrum is displaced towards the low-field side if the direction of the smallest g -value in the perpendicular plane coincides with that of the larger hyperfine splitting.

The foregoing considerations are independent of the exact nature of the radical sites. We can now consider what types of radical are present. As mentioned previously the spectrum for the parallel orientation shows only slight resolution of components even though the best resolution is expected for this direction. One factor to be considered is the degree of orientation of the radicals within the helices and of the helices within the fibres themselves. If only one type of radical were present, the lack of resolution could be accounted for by poor orientation. However, we should then expect a distribution of g -values leading to an asymmetric spectrum. The observed spectrum is nearly symmetric. If we suppose that several radical species are present, the overlapping hyperfine structure characteristic of each producing a poorly-resolved resultant, the g -values must lie within narrow limits to account for the relative lack of asymmetry. This would be the case if the radicals were π -electron systems located on the bases.

Now polarized infra-red investigations⁸ have shown that, at high humidities at least, the base planes in DNA are nearly normal to the helix axis. Theoretical considerations¹⁰ show that the g -values of such radicals normal to the plane of the π -electron system should be nearly equal to the free spin value, with slightly larger in-plane values. Reported experimental data¹¹ confirm this. The two in-plane values are usually unequal. On this picture we expect all the π -electron radicals to contribute nearly the same g -value along the helix axis so that a nearly symmetric spectrum results. At low water contents the bases are tilted off the helix axis; but even if this were by as much as 30° the g -value normal to the base planes would still make the largest contribution along the helix axis.

If this picture is correct the asymmetry of the perpendicular spectrum presumably arises both from asymmetry in contributions from any one radical species due to simultaneous g -value and hyperfine anisotropy as discussed above, and asymmetry arising from differences in the mean in-plane g -values of the various species supposed to be present. In practice, we cannot distinguish these two effects.

At the moment all these parameters are being examined with the view of obtaining quantitative definitions of the various classifications of cervical cells.

Fig. 1

BIOPHYSICS

Computer Recognition of Cervical Cell Nuclei

COMPUTER programmes which process data obtained by scanning 35-mm films of individual cervical cells are being tested in an attempt to obtain a quantitative definition of the differences between normal and malignant cells. The scanning instrument is of an electro-optical nature and has a digital output^{1,2}. It scans the photographic film in an array of points with each point yielding a number (between 0 and 128) the value of which depends on the emulsion density. The scan resolution can be varied from 4 lines each with 4 points to 256 lines each with 512 points. A typical single line scan (with 128 points) across a cervical cell nucleus is seen in Fig. 1. Normally these data are punched out automatically on paper tape, suitable for input to a Ferranti Sirius computer.

Having transformed the cell into an array of numbers, the problem now is to extract from it parameters which show significant differences between normal and malignant cells. It is essential for the solution of this problem that the original geometry of the cell nuclei be preserved. This has now been achieved in spite of the difficulties encountered when a cytoplasm is present.

The successful preservation of the geometry is illustrated by the graphs in Figs. 2 and 3, which were obtained after the computer had processed data obtained from scanning a normal cell and a 'malignant' cell. The object was to obtain a measure of the apparent thickness of the nuclear surface membrane. As a check on the validity of the computer programme the same sets of data were processed manually. These results are plotted beside the computer's selections.

The results for the nuclear surface membrane are taken from only a small part of the computer programme which is designed to extract a number of parameters characteristic of the cell. It was because of the ease of visual display of the nuclear surface membrane that it was selected for presentation here.

Distribution of Deoxyribonucleic Acid along Human Chromosomes

To the physicist the structure of the 46 normal human chromosomes is a problem analogous to that of atomic structure with as much fundamental significance. Although the appearance of artefacts and deviations resulting from variations in the technique of preparing samples of human chromosomes introduces, at this time, a degree of error into the results, it is possible to consider the measurement of the distribution of deoxyribonucleic acid (DNA) along the chromosome as essentially a purely physical problem of structure.

Elsewhere the electronic instrumentation involved in this work has been described in some detail¹⁻⁴. Briefly, the equipment consists essentially of a flying-spot scanner which scans a 35-mm transparency of (in this case) a human chromosome and converts the image into an array of numbers representing the grain densities involved. In the work described here the scan consists of 16 lines each containing 32 points and the grain density on any one point is represented by an integral number lying anywhere between 0 and 128. That is to say, the image of the human chromosome is scanned with 128 shades of grey.

The decision to limit the scan to a matrix of 16×32 was made for technical reasons only, and it is hoped later to increase this matrix as the equipment is improved. Nevertheless, even at present, using a 16×32 matrix and bearing in mind the limitations in the image due to diffraction and artefacts, the present matrix appears to be of considerable use in discovering the DNA distribution along the chromosomes. It is anticipated that, as the techniques of preparing the human chromosomes for this work steadily improve and artefacts are reduced and as the measuring equipment improves, it will be possible to make a more and more carefully detailed study of the DNA distribution, that is to say the physical structure of the human chromosome. The results described here may be regarded as a preliminary survey indicating the likely final development of the technique. Eventually, when the structure of the normal human chromosomes has been discovered in sufficient detail, the technique will be applied to a study of human chromosomes associated with different physiological conditions in human beings, particularly those involving malignant growths.

For convenience, chromosomes 4 and 12 were selected for study, as they are obviously different when viewed by the human eye. The transparencies of the chromosomes were inserted into the scanning instrument and the images of each of the chromosomes were transformed into a 16×32 matrix of numbers. These numbers were observed visually on a display tube as a check on the scanning procedure and then punched out on paper-tape. The paper-tapes were analysed by a Ferranti *Sirius* computer programmed to provide two forms of output data. The first form consists of a geometrical print-out, an array

of crosses indicating when a number was above an arbitrarily selected background-level. The result of such a print-out is shown in Fig. 1 for chromosomes 4 and 12. The second form in which the data appear from the *Sirius* computer consists of a series of 32 numbers; each of these numbers represents the sum total of all the numbers appearing in that particular vertical column of the original matrix. That is to say, these numbers represent the total DNA at a particular point along the chromosome, the distance along the chromosome being determined by which of the particular columns is being considered. This type of analysis is particularly interesting, as a graph of these 32 numbers gives essentially the DNA distribution along the chromosome, and typical results for chromosomes 4 and 12 are shown in Fig. 2.

Fig. 1

Fig. 2

It can be seen from Fig. 2 that the variation in DNA distribution along the two chromosomes is quite striking though it should be stated that these are preliminary results and there is some reason to believe that the staining used may in itself tend to be taken up with variable efficiency along the chromosome and therefore the stain density, which is of course the quantity being measured, is not a very accurate representation of the DNA distribution. This factor of the best choice of stain is being investigated at this laboratory, and it is hoped to find a stain which is sufficiently dark for scanning purposes and which also is taken up uniformly by the DNA present. Other results on chromosomes 4 and 12 show essentially the same type of structure as indicated in Fig. 2, and a programme is now under way to discover the essential features of the DNA distribution along all the 46 normal human chromosomes.

This work was made possible by research grants from the Medical Research Council and the Department of Scientific and Industrial Research. I thank Mr. J. Gray, Miss L. Robertson and Mr. G. Fraser, head of the Computer Unit at the University of Strathclyde, for their help.

BIOCHEMISTRY

Secretion of Newly Synthesized Insulin *in vitro*

Up to the present, there has been little information available concerning the rate at which newly synthesized protein hormones may be secreted, following the stimulation of endocrine glands. In recent work on the synthesis of insulin within pancreas slices, *in vitro*, it became of interest to determine whether or not newly synthesized insulin may be released directly into the incubation medium, or alternatively whether or not release of insulin might be delayed following its accumulation within β -granules. It has already been suggested by Lacy¹ that release of insulin from β -cells in response to glucose involves the movement of these granules to the cell surface, where they are released into blood vessels.

In the experiments to be reported, insulin was labelled by incorporation of label into pancreas slices *in vitro*, and its release into media containing glucose studied. When rabbit pancreas slices are incubated in physiological media, such as Krebs-Ringer bicarbonate, there is a small release of insulin at low glucose concentrations, though this is very greatly increased when the sugar concentration is raised. The increased release of insulin has been shown to reflect, at least qualitatively, the physiological behaviour of β -cells *in vivo*². To label the insulin, rabbit pancreas slices were incubated for 1 h with tritiated leucine of high specific activity by methods which have already been described in detail elsewhere^{3,4}. The incubation medium was then poured off and the pancreas slices washed thoroughly with fresh medium to remove excess radioactivity. The slices were then incubated for 30 min in a medium containing low concentrations of glucose (50 mg/100 ml.). For the final 1-h incubation phase, the medium was again discarded and the pancreas slices divided into two parts, one being incubated in a medium of low glucose concentration (50 mg/100 ml.), the other being incubated in medium containing a much higher concentration of glucose (250 mg/100 ml.). The medium was gassed with 95 per cent oxygen and 5 per cent carbon dioxide before each incubation phase. Insulin in the medium

derived from the final incubation phase was assayed by an immunological method⁵, and isolated from the medium so that its specific radioactivity might be determined.

The isolation of labelled insulin in the medium was carried out by an immunological technique, based on the precipitation of an insulin-antibody complex by means of an anti- γ -globulin. For this purpose, the whole medium was dialysed against distilled water and freeze dried. The proteins were then dissolved in a small volume of 0.003 M hydrochloric acid, and allowed to react with 0.5 ml. of a potent anti-serum made by repeated injection of crystalline ox insulin into guinea-pigs⁶. The whole γ -globulin fraction was then precipitated by the addition of a rabbit-anti-guinea-pig γ -globulin serum. The precipitate obtained was spun off, and after washing with saline, the insulin was regenerated from it by acid, and further purified by two-dimensional chromatography and electrophoresis on paper as previously described⁴. Insulin regenerated was assayed in the extract by immunoassay. The results of two representative incubations are shown in Table 1.

Table 1

Exp.	Insulin release into medium in final incubation phase (mU/flask/h)		Specific radioactivity of insulin extracted from medium (c.p.m./ μ g)	
	Low glucose	High glucose	Low glucose	High glucose
1	6.48	≈ 4	1,040	567
2	7.36	≈ 1	912	552

It will be seen that when pancreas slices are incubated in a medium containing a low concentration of glucose for 1.5 to 2.5 h after the start of labelling, there is some release of labelled insulin. However, when the final phase of incubation is in a medium of high glucose concentration, insulin release from the slices is increased several-fold while the specific activity of the insulin falls markedly. Very recently, similar results have been obtained from experiments in which the medium was extracted with acidic ethanol and the crude insulin precipitated with ether-ethanol⁷ before purification by the method already described here. In two such experiments the ratio of insulin output in the high glucose medium to that in medium of low glucose content was 4.08:1, while the ratio of specific activities of the insulin extracted was 0.35:1. It seems, therefore, that the greater part of the insulin secreted in response to a glucose stimulus has not been synthesized in the preceding 1.5-2.5 h. These results are in marked contrast with those obtained for the secretion from liver of newly synthesized albumin which is known not to be stored in granules⁸.

In pancreatic acinar tissue there is evidence from autoradiographic studies that newly synthesized secretory proteins appear first in the rough surfaced elements of the endoplasmic reticulum, then in the Golgi complex and finally after 1 h in the zymogen granules, from which they begin to be discharged 2 h after synthesis⁹. From the results described here, it seems possible there may be analogies between the secretion of newly synthesized insulin and the discharge of recently made secretory proteins.

We thank the Medical Research Council, the British Diabetic Association and British Insulin Manufacturers for financial assistance for various aspects of this work.

Hormonal Control of Lipid Concentration in Rat Heart and Gastrocnemius

In perfused rat heart and isolated rat diaphragm the rate of release and oxidation of fatty acids from muscle glycerides is increased by alloxan-diabetes¹. These changes in diabetes involve actions of growth hormone and corticosteroids in insulin-deficient rats because they are not seen in muscles of hypophysectomized diabetic rats unless the animals are treated with growth hormone and cortisol¹. As part of an investigation of the mechanisms of these changes we have investigated the effects of diabetes, hypophysectomy and treatment with growth hormone and cortisol on the concentrations of glycerides and phospholipids in rat heart and gastrocnemius (the latter as a representative skeletal muscle). The methods and procedure were as follows.

Rat hearts were perfused for 10 min with medium containing glucose (5.5 mM) and insulin (0.1 unit/ml.), and the excised ventricles frozen with a tissue clamp and powdered in a percussion mortar². Gastrocnemius muscle was frozen in acetone-solid carbon dioxide mixture and powdered after 10 min of hind-limb perfusion through the abdominal aorta with the foregoing medium containing glucose (11 mM) but no insulin. These perfusions remove blood and blood lipids. Details of induction of alloxan-diabetes and treatment with growth hormone and cortisol were as described elsewhere². The frozen muscle powder was extracted with chloroform/methanol (2:1 v/v) (15–30 ml./g) in a Potter homogenizer, allowed to stand at 0° for 2 h and centrifuged. The supernatant was shaken with 0.3 vol. of 4 mM magnesium chloride and phases separated by centrifugation after 30 min. The chloroform phase was evaporated to dryness at 70° and the residue taken up in about 7 ml. of chloroform and a sample (0.5 ml.) taken for determination of phospholipid-P (ref. 3), after evaporation of chloroform and oxidation with 0.15 ml. concentrated H₂SO₄/HClO₄ (2:1 v/v). The remainder was shaken with 0.5 g silicic acid to remove phospholipid⁴ (confirmed by assay of phospholipid-P). A sample of supernatant (4 ml.) was evaporated to dryness and glycerides separated by thin-layer chromatography on 'Silica Gel G' (Merck) using as solvent petroleum ether (fraction 40°–60°)/di-ethyl ether/methanol/acetic acid (90:20:2:3 v/v). As markers crude triolein (British Drug Houses, Ltd.) containing mono- and di-olein, and pure tripalmitin and mono-olein (Hormel Institute, University of Minnesota), were used (about 0.5 µmole). The *R_F* values of the separated classes were: mono-glycerides 0.05; diglycerides 0.45; triglycerides 0.90. The spots, located by markers, were scraped from the plate and extracted twice with 2 ml. of chloroform/methanol (2:1 v/v). The extract was evaporated to dryness at 70°, saponified with 0.5 ml. 4 per cent potassium hydroxide in 95 per cent ethanol for 30 min at 60°, acidified with 0.5 ml. 10 per cent HClO₄, neutralized with saturated KHCO₃, and KClO₄ separated by centrifugation at 0°. Glycerol was assayed enzymatically in the supernatant⁵. Recoveries (using 1-[¹⁴C]-palmitate labelled tripalmitin from the Radiochemical Centre, Amersham, added to extracts of heart) were in excess of 90 per cent. Recovery of mono-olein was in excess of 80 per cent. Contamination with phospholipid-P was less than 0.05 per cent.

The results are shown in Table 1. In the glyceride series the concentration of triglyceride was greatly in excess of that of di- and mono-glyceride, the concentration ratios being 140:1:6 in normal rat heart and 120:1:4 in normal rat gastrocnemius. These values indicate that loss of the first fatty acid may limit triglyceride breakdown in muscle. The concentration of triglyceride in heart and gastrocnemius was significantly increased by alloxan-diabetes. In hypophysectomized rats alloxan-diabetes failed to increase the triglyceride concentration unless the animals were treated with growth hormone

Table 1. GLYCERIDE AND PHOSPHOLIPID CONCENTRATIONS IN RAT HEART AND GASTROCNEMIUS

Rat	Tissue	Concentration µmoles/g dry wt. (Mean ± S.E.)			
		Triglyceride	Diglyceride	Monoglyceride	Phospholipid
Normal (6)	Heart	13.6 ± 1.4	0.1	0.6	184 ± 8
Alloxan-diabetic (6)		* 28.2 ± 1.9	0.6	0.7	163 ± 8
Hypophysectomized (6)		10.3 ± 1.3	0.4	0.7	143 ± 4
Hypophysectomized diabetic (6)		10.6 ± 0.9	0.3	0.7	154 ± 4
Hypophysectomized diabetic treated with growth hormone and cortisol (4)		* 22.9 ± 3.7	—	—	142 ± 5
Normal (8)	Gastrocnemius	12 ± 1.5	0.1	0.4	64 ± 2
Alloxan-diabetic (8)		26 ± 2.7	0.4	0.5	63 ± 1

* *P* < 0.01 versus control. No. of muscle samples given in parentheses.

and cortisol. The concentration of diglyceride (measured on pooled extracts) may also have been increased in alloxan-diabetes whereas the concentrations of mono-glyceride and phospholipids appeared to be unchanged. When hearts from normal rats were perfused for 60 min without substrate the triglyceride concentration fell from 18.7 ± 0.8 (8) to 8.7 ± 0.7 (8) (µmoles/g dry wt.; mean ± S.E. with number of hearts). No significant change in phospholipid was detected (186 ± 6–171 ± 7).

These observations lead us to conclude that heart muscle triglyceride is broken down during perfusion, thus providing fatty acid for oxidation⁶. Evidence for the location of this glyceride in muscle cells has been presented^{4,7}. The concentration of triglyceride, but not that of phospholipid, is increased by actions of growth hormone and cortisol in an insulin-deficient rat. Loss of the first fatty acid from triglyceride appears to limit breakdown in both normal and diabetic rats. The role of increased triglyceride concentration in accelerating lipolysis in diabetic muscle¹ and the source of muscle triglyceride (that is, whether derived from plasma glycerol or plasma non-esterified fatty acids) is under investigation.

We thank Mr. R. O. Law for help with perfusion of hind limbs and the British Diabetic Association, the Medical Research Council and the Royal Society for grants.

Acrylamide-gel Electrophoresis of β-Lactoglobulins stored in Solutions at pH 8.7

NATIVE β-lactoglobulins-A and -B, mol. wt. 35,500, can reversibly dissociate into sub-units of mol. wt. 17,750 in acidic¹ or alkaline² solutions. Aggregation of β-lactoglobulin-A to a tetramer structure has been observed¹ in solutions of pH 3.5–5.2 stored at 4° C. Irreversible denaturation of β-lactoglobulin occurs on heating³ neutral solutions above 65° C or on storage^{4,5} in alkaline solution at 25° (slowly in the pH range 8–9.5, more rapidly in solutions of higher pH). This denaturation was shown by changes in iso-electric solubility, optical rotation and light scattering; Tiselius electrophoresis in 'Veronal' (pH 8.4) buffer separated one, or occasionally two, faster-migrating components in addition to native β-lactoglobulin. An initial reversible splitting followed by irreversible aggregation was postulated³, but the nature and number of products formed were not studied further. Bingham, Krugman and Estermann⁶ recently noted that stored samples of β-lactoglobulin were separated by acrylamide disc electrophoresis⁷ into five bands whereas the fresh material split into only two bands; they gave no indication

the pH or composition of the β -lactoglobulin samples. This communication reports the progressive formation of at least eleven new species when β -lactoglobulin-A or -B or -A/B is stored in alkaline solution.

Twice-crystallized β -lactoglobulin-A and -B genetic variants were separately prepared⁸ from the milks of individually-typed Ayrshire cows⁹, and the A/B mixture from pooled herd milk, and each was freeze-dried. Each was electrophoretically pure (Fig. 1, a, b, c). The protein (0 mg) was dissolved in buffer solution (1 ml.) consisting of 0.076 M tris titrated to pH 8.7 with HCl and containing 0.10 M NaCl, and stored for several days at 2° C. Aliquots were removed daily for electrophoretic examination.

Sample solutions containing 100 μ g of β -lactoglobulin were separated by vertical disc electrophoresis⁷ in 11 per cent acrylamide-gel rods. The gels were prepared in 63 \times mm glass tubes using 'Cyanogum 41' (a mixture of acrylamide and methylenebisacrylamide; B.D.H., Ltd., Poole, England) dissolved in 0.076 M tris titrated to pH 8.6 with citric acid. The electrode tanks contained 0.3 M acetic acid titrated to pH 8.5 with sodium hydroxide¹⁰. It was not necessary to use the system⁷ of additional 'spacer' and 'sample' gels of weaker acrylamide concentration polymerized on top of the main gel column; the sample solution, made more dense by addition of 10 per cent sucrose and made visible by a trace of bromophenol blue, was layered directly on to the flat top of the 11 per cent acrylamide gel underneath the tank buffer solution. After electrophoresis for about 1 h at a constant current of 4 n.amp per gel rod, the rods were stained with amido black and electrolytically de-stained. The gel rods were stored in 7 per cent acetic acid, and photographed under strong back-lighting.

The electrophoretic patterns revealed a progressive formation of slower-migrating protein bands as the storage period increased. After one day about three new bands were visible (Fig. 1, d, e, f) and after seven days there were at least eleven sharp, slower-migrating bands. The β -A and β -B and β A/B mixture appeared to behave similarly, giving equal numbers of new bands at the same rate. After seven days storage nearly all the original β -

lactoglobulin bands had disappeared (Fig. 1, g, h, i) from the alkaline solution, but a control sample of 1 per cent β -lactoglobulin in 0.076 M tris titrated to pH 7.0 with hydrochloric acid still showed only the original (fast) β -lactoglobulin band and no new bands. Portions of 7-day-old alkaline solutions were titrated to pH 6.0 and examined after storage at this pH for several days further, but their electrophoretic patterns remained identical to those of the 7-day-old alkaline solution. This shows that the formation of the new species is induced by the high pH and is not reversible by subsequent acidification. Because of the molecular-sieving effect of 11 per cent acrylamide gels¹¹, it is probable that the slower-migrating bands represent progressively higher molecular weight aggregates formed slowly from either the original β -lactoglobulin molecules (mol. wt. 35,500) or their half-units. The amount of aggregation did not cause precipitation from the pH 8.7 solutions even after storage for several weeks, and no protein material remained on the origin of the gel rod after electrophoresis.
